Nalgonda Economics Forum

Website : nalgondaeconomicsforum.org

A teacher par excellence

Thanks to the free coaching imparted by Akkenapalli Meenaiah, students from rural background can now hope to secure a seat in Osmania University

Getting a seat in any post graduation course in Osmania university campus is always a tough task for rural graduates. Those who are keen to get a seat there have to spend money for tailor-made coaching classes.

Realising the need to impart free coaching, Akkenapalli Meenaiah, lecturer in Economics, Government Women's Degree College, Nalgonda, offered special training for students of Economics in the district. Indeed the effort yielded good results and seven out of 25 students got seats in PG courses.

While Maroju Kavita, a bright student of the Women's Degree College could secured eighth rank, three of her friends — Koorella Himavathi, Chintapalli Sailaja and Cherukuri Seshu Kumari — got seats in the OU campus, Hyderabad. They are all eligible to get a hostel facility thus getting a wonderful opportunity to prepare for competitive exams. Five other students are all set to get seats in other institutions. "But for Mr. Meenaiah coaching, I would not fared well in the entrance test," Ka-vitha said. The convener of the Nalgonda Economics Forum, Mr. Meenaiah said that a small initiative taken by him yielded very good result. He opted out of spot valuation to train his students to prepare for the entrance test. "I might have lost about Rs.10,000 for spending my time with the students but the ranks they got gave me an immense satisfaction," he maintained. Asked for the secret of success of his mission, Mr. Meenaiah, a native of Gopulaipallypalli in Narketpally mandal, said: "Every teacher must strive hard to - create interest on the subject among the students. Motivation works wonders among the rural students." It is remains to be seen whether other teachers emulate this concerned lecturer or not.

- S. RAMU, in Nalgonda

Foreword

The Nalgonda Economics Forum initiated its activity on the 12th of January 2007 and was subsequently registered on 10th May, 2013 with the registered number 297/13. This purely service oriented free coaching institution primarily aimed at training up students belonging to the rurally poor and socially and economically backward classes for admission through entrance into MA Economics course, but subsequently expanded to imparting training in a variety of areas of competitive examinations. When it came into existence some 18 years ago, almost every one of not more than ten students got selected to MA Economics course in different universities. And the Forum has now gradually, year after year, grown into fetching admission into PG Economics course to a bulky strength of as many as 800 candidates over these years. It is also to be noted that candidates trained at this Forum stood in the first rank in the PG Economics entrance examinations at Osmania University in 2009 and both at the Osmania and the Kakatiya universities subsequently in 2016, 2017 and 2018. The students of Nalgonda Economics Forum brought in the top three1st, 2nd and 3rd ranks followed by 7th, 8th, 9th and 10th ranks in CPGET -2020. In the year 2022 our students bagged state 1st, 7th and 10th ranks. We are happy to announce our forum student 10th ranker of CPGET-2022 Chanda Pranitha awarded Osmania University Gold Medal in Economics for the year 2023-24 The CPGET 2025 results released on 8th September, 2025, our forum got excellent results, first rank secured by S.Bhuvana Laxmi, Second Rank Secured by N.Ajay, Third Rank secured by A. Manasa and 6th Rank secured by Y. Lokesh. And our forum students also secured 12th, 13th, 14th, 17th & 20th Ranks.

As part of the extended areas of training programmes in different areas of competitive examinations, in addition to the basically mooted out MA Economics entrance training, the following are the achievements to our credit. Larger number of students trained here were qualified to SET and NET and **10 members of forum students were awarded Ph.D. in Economics.** In the year 2004, **41 candidates of our forum were selected as Govt Junior Lecturers, 10 candidates were selected as Degree Lecturers and 12 candidates wre selected as Junior Lecturers at Residential Degree & Junior Colleges** respectively in the state. A notable number of 100 above candidates trained here are now working as Economics faculty in different private unaided junior and degree colleges.

The Forum so far brought out Six Text Books in English and Three Text Books in Telugu for B.A Economics with ISBN number for the undergraduate students in the state, in tune with the choice based credit system that has come into vogue with the academic year 2019-20. Now we are brought Micro Economics 1st semester Text Book with ISBN number, as per new syllabus (2025-26) which is designed incorporating Artificial Intelligence concepts which are ruling present world Economy.

It is also to be mentioned here that the Forum, with a view to be in tune with the changing examination patterns year after year, has been keeping on updating itself and catering to the newest needs of the examination goers. It is particularly in this process that, apart from imparting training directly in classroom situations, Forum created a website of its own to help the students face the computer-based tests, besides providing study material on-line, bringing to the doorsteps the latest relevant information that boosts up the students' morale and self-confidence.As has already been mentioned, Forum created a website of its own to help the students in ways more than one and started providing study material on-line. The Forum started YouTube channel on 17th April 2020 and as yet uploaded 500 video lessons on Economics subject. This Forum channel was monetized on 21st November 2020. As on 18th August 2025, the channel bagged 5372 subscribers.

Another innovative achievement of the Nalgonda Economics Forum is facilitating Google Meet & Zoom meeting platforms, especially at a situation of disrupted communication on account of the prevalence of Covid -19 pandemic havoc. Thus Forum successfully conducted under this roof CPGET-2020, CPGET-2021, CPGET-2022, CPGET-2023, CPGET-2024, CPGET-2025 and Junior Lecturers & Degree Lecturers coaching classes for Economics.

As mentioned in one of the columns above, there has been a sustained growth of the student potentiality since the inception of the Forum. And, besides the unhindered growth in the size of the student strength, there has been a proportionately parallel increase of the achievements of the goals the Forum has been relentlessly endeavouring to meet year after year. More specifically, the training activity at the Forum has been continuing over so many years in no way uninterrupted at any moment of time. That there has always been an affirmatively evinced confidence in the reliability of our commitment to the interests' and aspirations of the students as well as to a scientifically reasoned approach to the curriculum activity stands proof positive to the continued scalability and sustainability of the motto before the Forum and its organizers.

Every year the Forum is incurring expenditure around Rs 70,000 (Seventy Tousand) to maintain Website, Zoom meet and softwere AMC, to meet this expenditure, Forum decided to raising around 10,00,000 (Ten Lakhs) for FDR from enrolling Life Members in the Forum. So far , Rs 4,20,198 has been contributed from 131 respected Life Members.

We are happy to note that this year's (2025) CPGET-2025 online coaching expenditure **Rs. 70,000 is jointly shared by NLN Foundation represented by Nati Srinivasulu NRI (Village Velminedu, Mandal Chityal Dist Nalgonda) & Serve the Pupils Foundation represented by Nati Ganesh. Our forum is highly thankful to them.** However, the recurrent source of funds is the Mallu Venkata Narsimhareddy (MVN) Vignana Kendram Trust. The same Trust, apart from facilitating total accommodational facilities for classrooms, library, etc, also provides from time to time all infrastructural facilities in a five-storied building of its own situated in the town of Nalgonda.

Dr. Akkenapally Meenaiah, M.A, M.Phil, Ph.D.
President Nalgonda Economics Forum

B.A. Micro Economics

Semester - I

Revised Syllabus 2025 - 26

Module-I : CONSUMER BEHAVIOUR

Consumer equilibrium in Ordinal utiliy Analysis (in behavioral Economics).Nudge theory, Role of AI in consumer Decision-making, demand elastisity in digital markets, Networks effects on consumer demand, Price, income and substitution Effects-On consumption.

Module-II : PRODUCTION ANALYSIS

Concepts of production function – Automation and AI in production, sustainable production method, Returns to scale- scope of economies in digital platforms and production effiency, Cobb-Douglas of Big data in production analysis.

Module-III : COST AND REVENUE ANALYSIS

Total cost, total fixed cost, total variable cost, average cost, average fixed cost, average variable cost, marginal cost and the relationship between average and marginal cost, Economies of scale- Digital and technological economies, Revenue concepts: total, average and marginal, relationship between Average revenue & marginal revenue, Revenue models indigital markets (Subscription, Freemium, Dynamic pricing).

Module--IV : MARKET STRUCTURE

Imperfect competion - Monopoly: Equilibrium of a monopolist with price discrimination, degrees of price discrimination, monopoly power in Tech firms, Antitrust Laws & Digital market monopolies, Monopolistic competition: Brand Loyalty and consumer psycology, social media, Oligopoly- collusion in Digital market places, Duopoly-Platform competion (Googel Apple, Uber vs Lyft) Digital market duopolies.

Module-V : ANALYSIS OF BUSINESS FIRM, AND PRICING STRATEGIES

Objectives of business firm: ESG (Environment, Social & Governace) consideration in Business strategy. Profit concepts: Accounting and economic prifit; break-even point –Role of AI in profit optimization, AI based pricing models

I N D E X

Module-1 : CONSUMER BEHAVIOUR **01-21**

1.1. Ordinal utility analysis-Assumptions 02
1.2. Indifference schedule and curve 03
1.3. Concept of Budget Line 05
1.4. Consumer Equilibrium 06
1.5. Introduction to the Nudge theory 07
1.6. Origins and Principles of Nudge theory 07
1.7. Application of Nudge theory 08
1.8. Benefits, Ethical considerations and criticisms on Nudge theory 09
1.9. Role of AI in consumer Decision making 10
1.10. Demand elasticity in Digital Markets 12
1.11. Network effects on consumer demand 14
1.12. Price Effect & Price consumption curve 15
1.13. Income Effect & Income consumption curve 17
1.14. Substitution Effect 19
1.15. Separation of price effect into income and substitution effects 20

Module-2 : PRODUCTION FUNCTION **22-38**

2.1 Production Function Equation 23
2.2. Factors of Production 23
2.3. Short-run Production Function 24
2.4. Law of Variable Proportions-Importance 24
2.5. Types of Automation 26
2.6. Role of AI in promotion of Automation 28
2.7. Importance of AI and Automation in Production 29
2.8. Sustainable Production Method 30
2.9. Returns to Scale 31
2.10. Economies of Scale in Digital Market 33
2.11. Cob-Douglas Production Function 35
2.12. Role of Big data in Production Analysis 36

Module - 3 : COST AND REVENUE ANALYSIS **39-59**

3.1. Cost Concepts 40
3.2. Short Run Costs Curves 41
3.3. Relation between AC and MC 44
3.4 Long run costs curves 45
3.5. Economies of Scale (Internal and External) 47
3.6. Digital and Technological Economies 49
3.7. Concepts of Revenue 50
3.8. Relationship between AR and MR in perfect 51

competition market
3.9. Relationship between AR and MR in imperfect 52
competition market
3.10. Subscription Model-Advantages and Disadvantages 54
3.11. Freemium Model-Advantages and Disadvantages 55
3.12. Dynamic Model-Advantages and Disadvantages 57

Module - 4 : MARKET STRUCTURE **60 - 78**

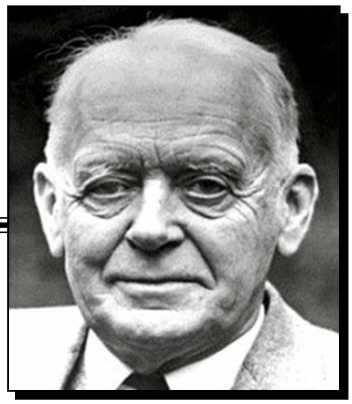
4.1. Features of Monopoly 61
4.2. Price determination and equilibrium
of the firm under Monopoly 62
4.3. Price Discrimination under Monopoly 65
4.4. Degrees of Price Discrimination 65
4.5. Monopoly power in Tech firms 67
4.6. Antitrust laws 68
4.7. Digital market monopolies 69
4.8. Features of monopolistic competition 70
4.9. Price determination and equilibrium of the
firm under Monopolistic competition 71
4.10. Brand loyalty Monopolistic competition 72
4.11. Consumer psychology in Monopolistic competition 73
4.12. Social media in Monopolistic competition 74
4.13. Collusion in digital market places 75
4.14. Platform competition in duopoly market 76
4.15. Digital market duopolies 77

Module - 5 : ANALYSIS OF BUSINESS FIRM,
& PRICING STRATEGIES **79-93**

5.1. Objectives of Business Firm 80
5.2. Benefits of ESG consideration in Business Strategy 81
5.3. Steps included integrating ESG in Business Strategy 83
5.4. Challenges in ESG integration 85
5.5. Meaning, Definitions, Formulas and of accounting
profit and Economic Profit 86
5.5.1. Differences between accounting profit and .....
Economic Profit 87
5.6. Break Even Point 88
5.7. Role of AI in Profit Optimisation 89
5.8. Working of AI based pricing models 90
5.9. Types of AI based pricing models 91
5.10. Advantages and Disadvantages of
AI based pricing models 92

Module

1



John Richard Hicks

8th April 1904 - 20th May, 1989

CONSUMER BEHAVIOUR

1.1. Ordinal utility analysis-Assumptions
1.2. Indifference schedule and curve
1.3. Budget line
1.4. Consumer equilibrium
1.5. Introduction to the Nudge theory
1.6. Origins and Principles of Nudge theory
1.7. Application of Nudge theory
1.8. Benefits, Ethical considerations & criticisms on Nudge theory
1.9. Role of AI in consumer Decision making
1.10. Demand elasticity in Digital Markets
1.11. Network effects on consumer demand
1.12. Price Effect & Price consumption curve
1.13. Income Effect & Income consumption curve
1.14. Substitution Effect
1.15. Separation of price effect into income and substitution effects

1.1. Ordinal utility analysis - Assumptions

The Ordinal Utility approach is based on the fact that the utility of a commodity cannot be measured in absolute quantity, but however, it will be possible for a consumer to tell subjectively whether the commodity derives more or less or equal satisfaction when compared to another.

The modern economists have discarded the concept of cardinal utility and instead applied ordinal utility approach to study the behaviour of the consumers. While the neoclassical economists believed that the utility can be measured and expressed in cardinal numbers, but the modern economists maintain that the utility being the psychological phenomena cannot be measured theoretically, quantitatively and even cardinally.

The modern economist, Hicks, in particular, have applied the ordinal utility concept to study the consumer behaviour. He introduced a tool of analysis called "Indifference Curve" to analyze the consumer behaviour. An indifference curve refers to the locus of points each showing different combinations of two substitutes which yield the same level of satisfaction and utility to the consumer.

Assumptions of Ordinal Utility Approach:

1. **Rationality:** It is assumed that the consumer is rational who aims at maximizing his level of satisfaction for given income and prices of goods and services, which he wish to consume. He is expected to take decisions consistent with this objective.
2. **Ordinal Utility:** The indifference curve assumes that the utility can only be expressed ordinals. This means the consumer can only tell his order of preference for the given goods and services.
3. **Transitivity and Consistency of Choice:** The consumer's choice is expected to be either transitive or consistent. The transitivity of choice means, if the consumer prefers commodity X to Y and Y to Z, then he must prefer commodity X to Z. In other words, if X = Y, Y = Z, then he must treat X = Z. The consistency of choice means that if a consumer prefers commodity X to Y at one point of time, he will not prefer commodity Y to X in another period or even will not consider them as equal.
4. **Nonsatiety:** It is assumed that the consumer has not reached the saturation point of any commodity and hence, he prefers larger quantities of all commodities.
5. **Diminishing Marginal Rate of Substitution (MRS):** The marginal rate of substitution refers to the rate at which the consumer is ready to substitute one commodity (X) for another commodity (Y) in such a way that his total satisfaction remains unchanged. The MRS is denoted as - Y/ X. The ordinal approach assumes that - Y/ X goes on diminishing if the consumer continues to substitute X for Y.

1.2. Indifference schedule and curve

Indifference curves are formulated based on ordinal utility analysis. They were originally introduced by British economist F.Y. Edgeworth in the book Mathematical Psychics: An Essay on the application of mathematics to the moral science - 1881 and American economist Irving Fisher (1892). Indifference curves were improved by the Italian economist Parito in 1906. It was developed by British economists J.R. Hicks and R.G.D. Allen in 1934. The indifference curve is the locus of the points where the consumer gets equal satisfaction by consuming different combination of X and Y goods.

Properties of Indifference Curve :

1. The slope of an indifference curve is negative, downward sloping, and from left to right.
2. An indifference curve is convex to the origin.
3. A higher indifference curve represents a higher level of satisfaction then lower indifference curve.
4. In between two indifference curves there can be a number of other indifference curves.
5. The numbers IC_1, IC_2, IC_3, IC_4... Etc. given to indifference curves are absolutely arbitrary.
6. Indifference curves can neither touch nor intersect each other.
7. An indifference curve cannot touch either axis.
8. Indifference curves are not necessarily parallel to each other.
9. If the two goods are perfect complements the indifference curve is L shaped.
10. If two goods are perfect substitutes, the indifference curve is a straight line with negative slope.

Meaning of Indifference Curve: When a consumer consumes various goods and services, then there are some combinations (bundles) which give him same satisfaction. The graphical representation of such combinations is termed as indifference curve.

Definition: "An indifference curve is the locus of different commodities giving the same level of satisfaction".

Indifference Map: An indifference map is a collection of indifference curves that represent different levels of satisfaction.Higher indifference curves represent higher level of satisfaction because higher indifference curves represent more quantities of both the goods or same quantity of one good and more quantity of other good.

The Marginal Rate of Substitution: The marginal rate of substitution is the rate of exchange between some units of goods X and Y which are equally preferred. The marginal rate of substitution of X for Y (MRS)xy is the amount of Y that will be given up for obtaining each additional unit of X. This rate is explained below in the following indifference schedule of Table and Figure in 1.1.

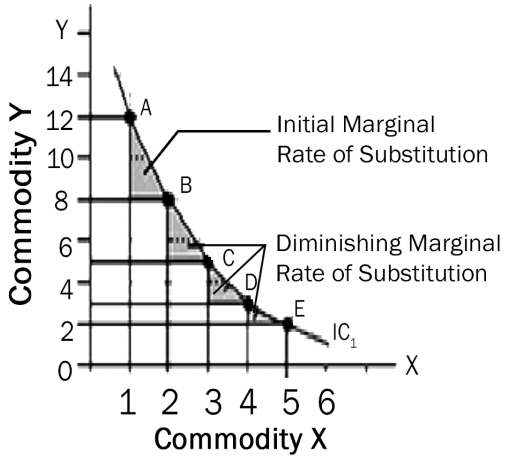


Figure 1.1

Combination	X Commodity	Y Commodity	MRS XY
A	**1**	**12**	**-**
B	**2**	**8**	**1:4**
C	**3**	**5**	**1:3**
D	**4**	**3**	**1:2**
E	**5**	**2**	**1:1**

Table 1.1

In the table all the 5 combinations gives same level of satisfaction to the consumer. In the A combination consumer is consuming 1, X commodity and 12, Y commodities. To have the B combination and yet to be at the same level of satisfaction, the consumer is prepared to forgo 4 units of Y for obtaining an extra unit of X. The marginal rate of substitution of X for Y is 4:1. The rate of substitution will then be the number of units of Y for which one unit of X is a substitute. As the consumer proceeds to have additional units of X, he is willing to give away less and less units of Y so that the marginal rate of substitution falls from 4:1 to 1:1.

In the figure 1.1. at point B on the indifference curve IC1, the consumer is willing to give up 4 units of Y to get an additional unit of X. As he moves along the curve, the consumer acquires more of X and less of Y. The amount of Y he is prepared to give up to get additional units of X becomes smaller and smaller. This behaviour of the consumer is known as the principle of diminishing marginal rate of substitution. The marginal rate of substitution of X for Y (MRSXY) is in fact the slope of the curve at a point on the indifference curve.

Thus $MRSxy = \frac{-\Delta Y}{\Delta Y}$

The principle of diminishing marginal rate of substitution is superior to the law of diminishing marginal utility. Because the Marshallian analysis is based on introspective cardinalism in which utility is measured quantitatively and is a single-commodity analysis. The principle of diminishing marginal rate of substitution is, however, scientific and realistic because it is free from the psychological quantitative measurement of utility analysis.

1.3. Concept of Budget Line

The knowledge of the concept of budget line is essential for understanding the theory of consumer's equilibrium. A higher indifference curve shows a higher level of satisfaction than a lower one. Therefore, a consumer in his attempt to maximize his satisfaction will try to reach the highest possible indifference curve.

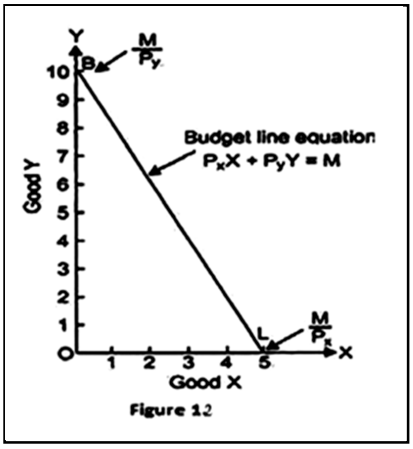

Figure 1.2

But in his pursuit of buying more and more goods and thus obtaining more and more satisfaction he has to work under two constraints; first, he has to pay the prices for the goods and, secondly, he has a limited money income with which to purchase the goods. Thus, how far he would go in for his purchases depends upon the prices of the goods and the money income which he has to spend on the goods. In order to explain consumer's equilibrium there is also the need for introducing into the indifference diagram the budget line which represents the prices of the goods and consumer's money income.

Suppose our consumer has got income of Rs. 50 to spend on goods X and Y. Let the price of the good X in market be Rs. 10 per unit and that of Y Rs. 5 per unit. If the consumer spends his whole income of Rs. 50 on good X, he would buy 5 units of X; if he spends his whole income of Rs. 50 on good Y he would buy 10 units of Y. If a straight line joining 5X and 10Y is drawn, we will get what is called the price line or the budget line. This budget line shows all those combinations of two goods which the consumer can buy spending his given money income on the two goods at their given prices. In the figure 1.2 with Rs. 50 and the prices of X and Y being Rs. 10 and Rs. 5 respectively the consumer can buy 10 - Y and 0 (zero) - X, or 8 - Y and 1 - X; or 6 - Y and 2 - X, or 4 - Y and 3 -X etc.

In other words, he can buy any combination that lies on the budget line with his given money income and given prices of the goods. It is also important to remember that the intercept OB on the Y-axis in Fig. equals the amount of his entire income divided by the price of commodity Y. That is, OB = M/Py. Likewise, the intercept OL on the X-axis

measures the total income divided by the price of commodity X. Thus OL = M/Px.

The budget line can be written algebraically as follows: PxX + PyY = M , Where Px and Py denote prices of goods X and Y respectively and M stands for money income. The

budget-line equation implies that, given the money income of the consumer and prices of the two goods, every combination lying on the budget line will cost the same amount of money and can therefore be purchased with the given income. The budget line can be defined as a set of combinations of two commodities that can be purchased if whole of a given income is spent on them and its slope is equal to the negative of the price ratio.

1.4. Consumer's Equilibrium

Consumer equilibrium refers to a situation, in which a consumer derives maximum satisfaction, with no intention to change it and subject to given prices and his given income. The point of maximum satisfaction is achieved by studying indifference map and budget line together. On an indifference map, higher indifference curve represents a higher level of satisfaction than any lower indifference curve. So, a consumer always tries to remain at the highest possible indifference curve, subject to his budget constraint.

Conditions of Consumer's Equilibrium: The consumer's equilibrium under the indifference curve theory must meet the following two conditions:

(i) MRSXY = Ratio of prices or PX/PY : Let the two goods be X and Y. The first condition for consumer's equilibrium is that, MRSXY = PX/PY

(ii) MRS continuously falls: The second condition for consumer's equilibrium is that MRS must be diminishing at the point of equilibrium, i.e. the indifference curve must be convex to the origin at the point of equilibrium. Unless MRS continuously falls, the equilibrium cannot be established. Thus, both the conditions need to be fulfilled for a consumer to be in equilibrium.

Let us now understand this with the help of a diagram:

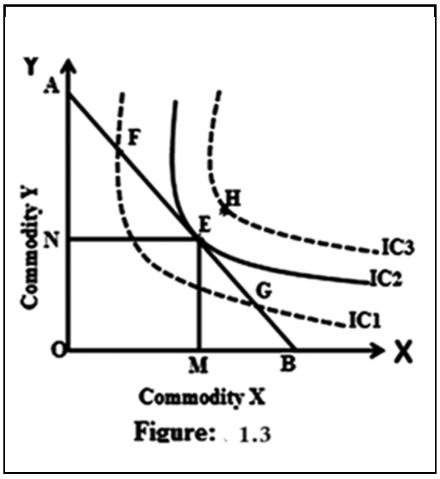

Figure: 1.3

In the figure 1.3, IC1, IC2 and IC3 are the three indifference curves and AB is the budget line. With the constraint of budget line, the highest indifference curve, which a consumer can reach, is IC2. The budget line is tangent to indifference curve IC2 at point 'E'. This is the point of consumer equilibrium, where the consumer purchases OM quantity of commodity 'X' and ON quantity of commodity 'Y. The other points on the budget line to the left (F) or right (G) of point 'E' will lie on lower indifference curve IC1 and thus indicate a lower level of satisfaction. Whereas point (H) on IC3 indifference curve is far away from consumer budget line AB. The budget line AB is tangent to IC2 indifference curve at point 'E', consumer maximizes his satisfaction at this point, when both the conditions of consumer's equilibrium are satisfied.

1.5. Introduction to the Nudge theory

Behavioral economics is grounded in empirical observations of human behavior, which have demonstrated that people do not always make what neoclassical economists consider the "rational" or "optimal" decision, even if they have the information and the tools available to do so. Behavioral economics has expanded since the 1980s, but it has a long history: According to Thaler, some important ideas in the field can be traced back to 18th-century Scottish economist Adam Smith.

Adam Smith is often remembered for the concept of an "invisible hand" that guides an overall economy to prosperity if each individual makes their own self-interested decisions a key concept in classical and neoclassical economics. But he also recognized that people are often overconfident in their own abilities, more afraid of losing than they are eager to win and more likely to pursue short-term than long-term benefits. These ideas (overconfidence, loss aversion and self-control) are foundational concepts in behavioral economics today.

In the 1980s, Richard Thaler began to build on the work of Tversky and Kahneman, with whom he collaborated extensively. Now the Charles R. Walgreen Distinguished Service Professor of Behavioral Science and Economics at the Booth School of Business, he is today considered a founder of the field of behavioral economics.

Behavioral economics combines elements of economics and psychology to understand how and why people behave the way they do in the real world. It differs from neoclassical economics, which assumes that most people have well-defined preferences and make well-informed, self-interested decisions based on those preferences.

1.6. Origins and Principles of Nudge theory

The Nudge theory, developed by Richard Thaler and Cass Sunstein in their 2008 book Nudge: Improving Decisions about Health, Wealth, and Happiness is a concept in behavioral economics that proposes positive reinforcement and indirect suggestions to influence behavior and decision-making without limiting freedom of choice.

Origins: The Nudge theory emerged from the intersection of behavioral economics, psychology, and public policy. Thaler and Sunstein drew on research showing that humans often act irrationally or against their best interests due to cognitive biases. They argued that by "nudging" people toward better decisions, policymakers and institutions could improve outcomes in areas like health, finance, and education.

Key Principles :

1. **Libertarian Paternalism:** Nudges aim to guide people toward beneficial choices while preserving their freedom to decide otherwise.
2. **Choice Architecture:** The design of the environment in which decisions are made can significantly influence outcomes. Nudges alter this architecture to encourage better choices.
3. **Behavioral Insights:** Nudges are based on understanding human behavior and cognitive biases, such as inertia, loss aversion, and social proof.
4. **Soft Interventions:** Unlike mandates or bans, nudges use subtle, non-coercive methods to influence behavior.

Examples :

1. **Default Options:** Automatically enrolling employees in retirement savings plans increases participation rates.
2. **Visual Cues:** Placing healthier foods at eye level in a cafeteria encourages better eating habits.
3. **Social Norms:** Informing households about their energy consumption relative to neighbors can reduce energy use.

1.7. Application of Nudge theory

Nudge theory is applied in various fields, including public policy, healthcare, finance, and marketing, to promote better decision-making and improve societal outcomes. Some examples include:

1. Public Policy :

1) **Retirement Savings:** Automatic enrollment in retirement plans increases participation rates.
2) **Health:** Placing healthier food options at eye level in cafeterias promotes better eating habits.
3) **Environment:** Providing energy consumption comparisons to neighbors reduces energy use.

2. Healthcare :

1) **Medication Adherence:** Simplifying medication packaging and reminders improves adherence.
2) **Vaccination**: Sending reminders and making vaccination appointments easy to schedule increases vaccination rates.

3. Finance :

1) **Savings:** Automatic savings plans and round-up features encourage saving.
2) **Investing:** Providing clear, simple investment options and default investment plans helps investors make informed decisions.

4. Marketing :

1) **Product Placement:** Strategically placing products in stores or online influences purchasing decisions.
2) **Scarcity Messaging:** Using messages like "limited time offer" encourages purchases

5. Education :

1) **Default Options:** Setting default deadlines for assignments or automatically enrolling students in beneficial programs improves engagement.
2) **Goal Setting:** Encouraging students to set specific, achievable goals improves motivation and performance.

6. Workplace :

1) **Wellness Programs:** Offering default enrollment in wellness programs or providing healthy snacks promotes employee well-being.
2) **Productivity:** Implementing structured scheduling and reminders improves employee productivity. These applications demonstrate how subtle changes in choice architecture can significantly impact behavior and outcomes.

1.8. Benefits, Ethical considerations and criticisms on Nudge theory Benefits

1. **Improved Decision-Making:** Nudges help individuals make better choices without restricting their freedom.
2. **Increased Participation:** Automatic enrollment in programs (e.g., retirement savings) boosts participation rates.
3. **Behavioral Change:** Nudges promote positive behaviors, such as healthier eating or reduced energy **consumption.**
4. **Cost-Effective:** Nudges can be more efficient and less expensive than traditional policy interventions.
5. **Flexibility:** Nudges can be tailored to specific contexts and populations

Ethical Considerations :

1. **Manipulation:** Critics argue that nudges can manipulate individuals without their awareness or consent.
2. **Autonomy:** Nudges may undermine individual autonomy by influencing decisions without explicit consent.
3. **Transparency:** Lack of transparency in nudge implementation can erode trust.
4. **Equity:** Nudges may disproportionately benefit certain groups while neglecting others.
5. **Paternalism:** Nudges can be seen as paternalistic, imposing certain values or choices on individuals.

Criticisms of Nudge Theory :

1. **Lack of Evidence:** Some argue that the evidence supporting nudge effectiveness is limited or mixed.
2. **Context Dependence:** Nudges may not work universally and can be context-dependent.
3. **Overemphasis on Individual Responsibility:** Nudges may shift responsibility from institutions to individuals.
4. **Potential for Abuse:** Nudges can be used to manipulate people for commercial or political gain.
5. **Limited Impact:** Nudges may have limited long-term impact or fail to address underlying structural issues.

Addressing Criticisms and Ethical Concerns :

1. **Transparency:** Ensure transparency in nudge implementation and communicate clearly with individuals.
2. **Empowerment:** Design nudges that empower individuals to make informed decisions.
3. **Evidence-Based Design:** Ground nudge design in robust evidence and testing.
4. **Equity and Inclusivity:** Consider the potential impact on diverse populations and strive for equity.
5. **Ongoing Evaluation:** Continuously evaluate and refine nudges to ensure they remain effective and ethical. By acknowledging these benefits, ethical considerations, and criticisms, policymakers and practitioners can design and implement nudges that promote positive outcomes while respecting individual autonomy and dignity.

1.9. Role of AI in Consumer Decision Making

The goal of artificial intelligence (AI), a broad field of computer science, is to create intelligent machines that can carry out tasks that normally call for human intelligence. Even though artificial intelligence (AI) is an interdisciplinary discipline with many different techniques, developments in machine learning and deep learning in particular are revolutionizing almost every area of the IT sector. Machines with artificial intelligence can take off or even surpass human mental capacities. As self-driving cars become more usual and generative AI tools like ChatGPT and Google's Bard proliferate, AI is becoming a more integral part of daily life and is a field that businesses in every sector are investing in.

Artificial intelligence (AI) has a significant impact on customer purchasing Behaviour and is changing the conventional retail environment. With the use of AI technologies, organizations can now obtain deep insights into customer preferences, allowing for more individualized and focused marketing strategies. Algorithms for making recommendations examine past actions and preferences to provide users with personalized recommendations that improve their online purchasing experience. Furthermore, AI-powered chat bots and virtual assistants offer on-demand support, assisting customers with decision-making and answering questions.

In addition to streamlining the search and selection process, speech and picture recognition technologies have made it possible for customers to engage with products in novel ways before making a purchase. AI also helps to optimize supply chains, pricing policies, and fraud detection, which promotes a safer and more effective online shopping experience. Businesses that use AI stand to not only satisfy but also anticipate customer wants as customers embrace these technological breakthroughs more and more. This will ultimately influence and shape consumers' purchasing Behaviour in the ever-changing world of modern commerce.

AI plays a significant role in consumer decision-making, particularly in e-commerce, by providing personalized recommendations, enhancing shopping efficiency, and facilitating informed choices. Here are some key ways AI influences consumer decisions:

1. **Personalized Recommendations:** AI algorithms analyze consumer behavior, preferences, and purchase history to suggest relevant products, enabling informed purchasing decisions. For instance, according to a Lazada study 88% of consumers make purchase decisions using AI-powered product recommendations.
2. **Efficient Shopping Experience:** AI-driven chat bots provide instant customer support, reducing waiting times and making shopping more efficient. This leads to increased customer satisfaction and loyalty.
3. **Informed Decision-Making:** AI analyzes complex product information, such as sustainability metrics, enabling consumers to make informed decisions that align

with their values. AI-powered predictive analytics also forecasts customer behavior, allowing businesses to tailor experiences and suggest actions that resonate with individual preferences.

4. **Sustainable Consumption:** AI empowers consumers to make sustainable choices by personalizing information, recommending eco-friendly options, and tracking environmental impact.

5. **Data-Driven Insights:** AI processes large volumes of data to identify patterns, trends, and correlations, enabling businesses to make data-driven decisions based on accurate and timely insights.

6. **Product Discovery:** AI-powered tools help consumers find products quickly and efficiently.

7. **Customer Service:** AI-driven chat bots handle customer inquiries, provide support, and offer personalized recommendations.

8. **Predictive Analytics:** AI forecasts customer behavior, market trends, and demand fluctuations, enabling businesses to make proactive decisions.

9. **Pricing Strategies:** AI algorithms analyze market dynamics, competitor pricing, and customer behavior to determine optimal pricing strategies. Overall, AI enhances consumer decision-making by providing personalized experiences, streamlining shopping processes, and facilitating informed choices.

It should be noted that artificial intelligence (AI) is having a revolutionary effect on how consumers interact with products and make judgments about what to buy. One significant discovery focuses on the effectiveness of tailored recommendations, which is a fundamental component of AI applications in the retail sector. Recommendation engines powered by artificial intelligence (AI) and advanced machine learning algorithms mine enormous databases that include user preferences, browsing, and purchase history.

Recommendation engines are becoming increasingly dependent on the strategic application of AI to meet and beyond customer expectations. This process is greatly aided by AI's data analysis skills, which offer insights that let companies instantly recognize and adjust to changing customer preferences. The incorporation of AI transforms the way consumers find, assess, and choose items, going beyond simple process automation. The modern shopping experience has come to anticipate customization, and companies that use AI are well-positioned to meet this expectation. AI technology will become more and more influential in shaping consumer Behaviour as it develops, therefore companies looking to stay ahead in a competitive and dynamic market will need to take a proactive and strategic approach. In the end, the combination of AI and consumer purchasing Behaviour is a powerful force that is changing the face of business in the digital era.

1.10. Demand Elasticity in Digital Markets

One of the key concepts in economics and marketing is elasticity of demand, which measures how responsive consumers are to changes in the price or other factors affecting the demand for a product or service. Understanding elasticity of demand can help marketers design effective strategies to maximize their revenue, profit, and market share.

Elasticity of demand is the ratio of the percentage change in the quantity demanded to the percentage change in the price or another factor affecting demand. There are several factors that influence how elastic or inelastic the demand for a product or service is. Some of the main determinants are:

1. The availability of substitutes: The more substitutes there are for a product or service, the more elastic the demand will be, as consumers can easily switch to another option if the price or quality changes. For example, the demand for soft drinks is elastic, as there are many other beverages that consumers can choose from.

2. The proportion of income spent on the product or service: The higher the proportion of income that consumers spend on a product or service, the more elastic the demand will be, as consumers will be more sensitive to changes in the price or quality. For example, the demand for housing is elastic, as it represents a large share of consumers' income.

3. The time horizon: The longer the time period that consumer has to adjust their behavior, the more elastic the demand will be, as consumers can find alternatives or change their preferences over time.

4. Necessity: Essential products tend to have inelastic demand, while luxury products have elastic demand.

5. Preferences: Consumer preferences and loyalty can influence demand elasticity.

Implications for Businesses :

1. Pricing Strategies: Businesses can use elasticity insights to optimize pricing and maximize revenue. For elastic products, reducing prices can increase sales and revenue, while for inelastic products; increasing prices may not significantly affect demand.

2. Revenue Maximization: Understanding demand elasticity helps businesses identify opportunities to increase revenue by adjusting prices or investing in advertising.

3. Marketing Strategies: Businesses can use elasticity insights to target specific customer segments and modify their marketing efforts.

Elasticity of demand can help marketers determine the optimal price and quantity for their product or service, as well as the impact of changes in the market conditions or the marketing mix on their revenue, profit, and market share. Some of the implications of elasticity of demand for marketing are:

1. The demand for a product or service is elastic; marketers can increase their revenue and profit by lowering the price, as this will stimulate a large increase in the quantity demanded. Conversely, if the demand for a product or service is inelastic, marketers can increase their revenue and profit by raising the price, as this will cause a small decrease in the quantity demanded.

2. The demand for a product or service is elastic, marketers should invest more in advertising, promotion, and product differentiation, as these can increase the demand and make it more inelastic, allowing them to charge a higher price and increase their revenue and profit. Conversely, if the demand for a product or service is inelastic, marketers should invest less in advertising, promotion, and product differentiation, as these will have a small effect on the demand and may not justify the cost.
3. The demand for a product or service is elastic, marketers should be more responsive to changes in the market conditions or the marketing mix of their competitors, as these can have a large impact on their demand and market share. Conversely, if the demand for a product or service is inelastic, marketers should be less responsive to changes in the market conditions or the marketing mix of their competitors, as these will have a small impact on their demand and market share.
There are four main types of elasticity of demand that marketers need to consider:

1. Price elasticity of Demand: Price elasticity of demand measures how sensitive consumers are to changes in the price of a product or service. It is calculated by dividing the percentage change in quantity demanded by the percentage change in price. A product or service is said to have elastic demand if the percentage change in quantity demanded is greater than the percentage change in price, meaning that consumers are very responsive to price changes. Marketers need to know the price elasticity of demand of their products or services to determine the optimal pricing strategy.

2. Income elasticity of demand: Income elasticity of demand measures how sensitive consumers are to changes in their income. It is calculated by dividing the percentage change in quantity demanded by the percentage change in income. A product or service is said to have positive income elasticity of demand if the percentage change in quantity demanded is positive when the percentage change in income is positive, meaning that consumers buy more of the product or service when their income increases. On the other hand, a product or service is said to have negative income elasticity of demand if the percentage change in quantity demanded is negative when the percentage change in income is positive, meaning that consumers buy less of the product or service when their income increases.

3. Cross elasticity of demand: Cross elasticity of demand measures how sensitive consumers are to changes in the price of a related product or service. It is calculated by dividing the percentage change in quantity demanded of one product or service by the percentage change in price of another product or service. A product or service is said to have positive cross elasticity of demand if the percentage change in quantity demanded of one product or service is positive when the percentage change in price of another product or service is positive, meaning that the two products or services are substitutes. Marketers need to know the cross elasticity of demand of their products or services to determine the competitive strategy and the promotional strategy.

4. Advertising elasticity: Advertising elasticity of demand measures how sensitive consumers are to changes in the advertising expenditure of a product or service. It is calculated by dividing the percentage change in quantity demanded by the percentage change in advertising expenditure. A product or service is said to have high advertising elasticity of demand if the percentage change in quantity demanded is greater than the percentage change in advertising expenditure, meaning that consumers are very responsive to advertising. On the other hand, a product or service is said to have low advertising elasticity of demand if the percentage change in quantity demanded is less than the percentage change in advertising expenditure, meaning that consumers are not very responsive to advertising.

1.11. Network Effects on Consumer Demand

Network effects refer to the phenomenon where the value or utility of a product, service, or platform increases as more people use it. This can create a self-reinforcing cycle, where increased adoption leads to greater value, which in turn attract even more users.The network effect occurs when the quantity demanded by a consumer at a given price is influenced by the market demand for the product.

Network effects significantly influence consumer demand by creating a self-reinforcing cycle. Where the value of a product or service increases with the number of users.

Types of Network Effects :-

1. Direct Network Effects: The value of a product or service increases directly with the number of users, such as social media platforms like Face book or LinkedIn.

2. Indirect Network Effects: The value increases due to the availability of complementary products or services, like smart phones and apps.

3. Cross-Side Network Effects: The value depends on the number of users on the other side of the market, such as marketplaces like eBay or Amazon.

4. Multi-Sided Network Effects: Platforms that bring together different types of users, like buyers and sellers, create a robust ecosystem.

Network - Impact on Consumer Demand :-

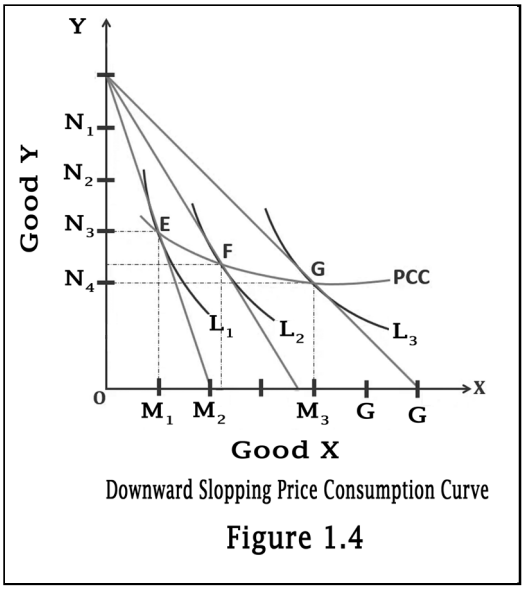
1. **Increased Value:** As more users join a network, the service becomes more valuable, attracting even more users.
2. **Word-of-Mouth Influence:** Online consumer networks can make or break a product's reputation, with positive reviews and viral posts leading to increased demand.
3. **Social Proof:** Consumer networks empower individuals to share their experiences and reviews, influencing purchasing decisions of others within their network.
4. **Social Media:** Instagram Shopping allows users to buy products featured in posts and stories, seamlessly blending social browsing with e-commerce.
5. **E-commerce:** Xiaomi's flash sales generate buzz and sell out products in minutes, demonstrating the power of network effects in driving demand.
6. **Marketplaces:** Platforms like Uber and Airbnb thrive on network effects, where the number of service providers and users reinforce each other, creating a robust ecosystem.

Network - Benefits :

1. **Increased Value:** More users create more value for each individual user.
2. **Competitive Advantage:** Strong network effects can make it difficult for competitors to enter the market.
3. **Growth:** Network effects can drive rapid growth and adoption.

   Ensuring the quality of interactions and services as the network grows. Understanding network effects is crucial for businesses to leverage this phenomenon and create successful, scalable products and services.

1.12. Price Effect & Price Consumption Curve



Downward Slopping Price Consumption Curve

Figure 1.4

When, the price of good changes, the consumer would be either better off or worse off than before, depending upon whether the price falls or rises. In other words, as a result of change in price of a good, his equilibrium position would lie at a higher indifference curve in case of the fall in price and at a lower indifference curve in case of the rise in price.

Price effect is shown in adjoining figure 1.4. With given prices of goods X and Y, and a given money income as represented by the budget line PL_1, the consumer is in equilibrium at Q on indifference curve IC_1. In this equilibrium position at Q, he is buying OM_1 of X and ON_1 of Y. Let price of good X fall, price of Y and his money income remaining unchanged. As a result of this price change, budget line shifts to the position PL_2. The consumer is now in equilibrium at R on a higher indifference curve IC_2 and is buying OM_2 of X and ON_2 of Y. He has thus become better off, that is, his level of satisfaction has increased as a consequence of the fall in the price of good X. Suppose that price of X further falls so that PL_3 is now the relevant price line. With budget line PL3 the consumer is in equilibrium at S on indifference curve IC_3 where he has OM_3 of X and ON_3 of Y. If the price of good X falls still further so that budget line now takes the position of PL_4, the consumer now attains equilibrium at T on indifference curve IC4 and has OM4 of X and ON_4 of Y.

When all the equilibrium points such as Q, R, S, and T are joined together, we get what is called Price Consumption Curve (PCC). Price consumption curve traces out the price effect. It shows how the changes in price of good X will affect the consumer's purchases of X, price of Y, his tastes and money income remaining unaltered. In figure price consumption curve (PCC) is sloping downward. Downward sloping price consumption curve for good X means that as the price of good X falls, the consumer purchases a larger quantity of good X and a smaller quantity of good Y. This is quite evident from figure.

In elasticity of demand, we obtain downward-sloping price consumption curve for good X when demand for it is elastic (i.e., price elasticity is greater than one). But downward sloping is one possible shape of price consumption curve. Price consumption curve can have other shapes also.

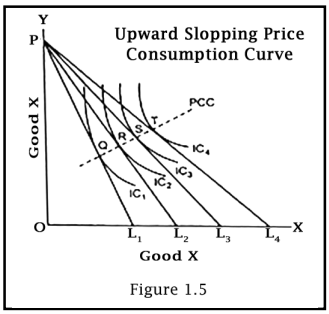


Figure 1.5

In adjoining figure 1.5 upward-sloping price consumption curve is shown. Upward-sloping price consumption curve for X means that when the price of good X falls, the quantity demanded of both goods X and Y rises. We obtain the upward-sloping price consumption curve for good X when the demand for good is inelastic, (i.e., price elasticity is less than one).

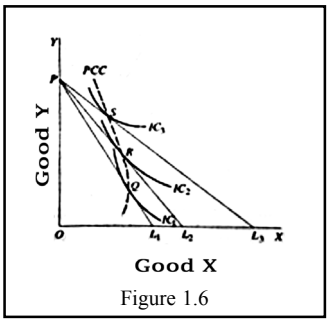

Figure 1.6

Price consumption curve can also have a backward- sloping shape, which is depicted in adjoining figure 1.6. Backward-sloping price consumption curve for good X indicates that when price of X falls, after a point smaller quantity of it is demanded or purchased. This is true in case of exceptional type of goods called Giffen Goods.

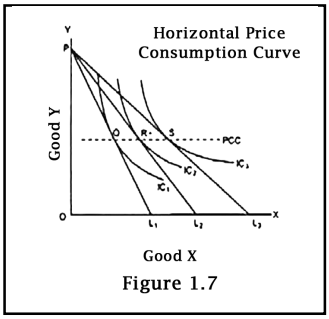

Figure 1.7

Price consumption curve for a good can take horizontal shape too. It means that when the price of the good X declines, its quantity purchased rises proportionately but quantity purchased of Y remains the same. Horizontal price consumption curve is shown in figure 1.7. We obtain horizontal price consumption curve of good X when the price elasticity of demand for good X is equal to unity.

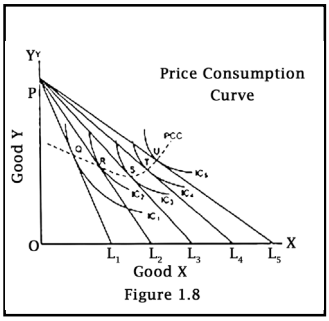

Figure 1.8

It is rarely found that price consumption curve slopes downward throughout or slopes upward throughout or slopes backward throughout. More generally, price consumption curve has different slopes at different price ranges. At higher price levels it generally slopes downward, and it may then have a horizontal shape for some price ranges but ultimately it will be sloping upward. For some price ranges it can be backward sloping as in case of Giffen goods. A price consumption curve which has different shapes or slopes at different price ranges is drawn in figure 1.8

1.13. Income Effect - Income Consumption Curve

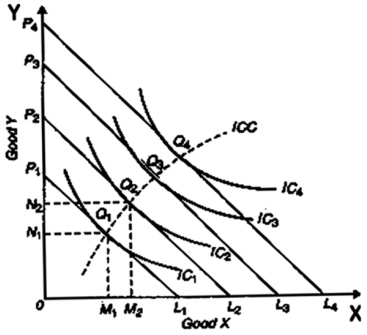

Figure 1.9

With given money income to spend on goods, given prices of the two goods and given an indifference map, the consumer will be in equilibrium at a point in an indifference map. We are interested in knowing how the consumer will react in regard to his purchases

of the goods when his money income changes, prices of the goods and his tastes and preferences remaining unchanged. Income effect shows this reaction of the consumer. Thus, the income effect means the change in consumer's purchases of the goods as a result of a change in his money income. Income effect is illustrated in adjoining figure 1.9

With given prices and a given money income as indicated by the budget line P_1L_1 the consumer is initially in equilibrium at point Q_1 on the indifference curve IC_1 and is having OM_1 of X and ON_1 of Y. Now suppose that income of the consumer increases. With his increased income, he would be able to purchase larger quantities of both the goods.

As a result, budget line will shift upward and will be parallel to the original budget line P_1L_1. Let us assume that the consumer's money income increases by such an amount that the new budget line is P_2L_2, the consumer is in equilibrium at point Q_2 on indifference curves IC2 and is buying OM2 of X and ON2 of Y.

Thus as a result of the increase in his income the consumer buys more quantity of both the goods Since he is on the higher indifference curve IC_2 he will be better off than before i.e., his satisfaction will increase. If his income increases further so that the budget line shifts to P3L3, the consumer is in equilibrium at point Q3 on indifference curve IC3 and is having greater quantity of both the goods than at Q_2.

Consequently, his satisfaction further increases. In the figure the consumer's equilibrium is shown at a still further higher level of income and it will be seen that the consumer is in equilibrium at Q_4 on indifference curves IC_4 when the budget line shifts to P_4L_4. As the consumer's income increases, he switches to higher indifference curves and as a consequence enjoys higher levels of satisfaction.

If now various points Q1, Q2, Q3 and Q4 showing consumer's equilibrium at various levels of income are joined together, we will get what is called Income Consumption

Curve (ICC). Income consumption curve is thus the locus of equilibrium points at various levels of consumer's income. Income effect can either be positive or negative.

Income effect for a good is said to be positive when with the increase in income of the consumer, his consumption of the good also increases. This is the normal good case. When the income effect of both the goods represented on the two axes of the figure is

positive, the income consumption curve ICC will slope upward to the right as in the figure. Only the upward- sloping income consumption curve can show rising consumption of the two goods as income increases.

However, for some goods, income effect is negative. Income effect for a good is said to be negative when with the increases in his income, the consumer reduces his

consumption of the good. Such goods for which income effect is negative are called Inferior Goods. This is because the goods whose consumption falls as income of the consumer rises are considered to be some way 'inferior' by the consumer and therefore he substitutes superior goods for them when his income rises.

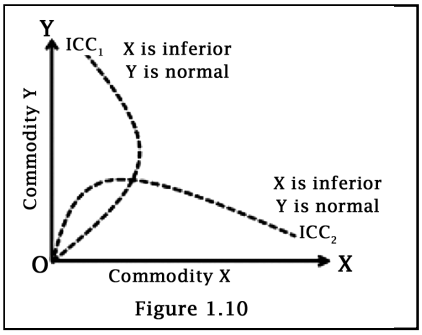

Figure 1.10

In case of inferior goods, indifference map would be such as to yield income consumption curve which either slopes backward (i.e., toward the left) or downward to the right as in figure 1.10. It would be noticed from the figure that income effect becomes negative only after a point. If income effect for good X is negative, income consumption curve will slope backward to the left as ICC_1 in figure. If good Y happens to be an inferior good and income consumption curve will bend towards X-axis as shown by ICC_2 in figure.

Normal goods can be either necessities or luxuries depending upon whether the quantities purchased of the goods by the consumers increase less than or more than proportionately to the increases in income. If the quantity purchased of a commodity rises less than proportionately to the increases in consumer's income, the commodity is known as a necessity.

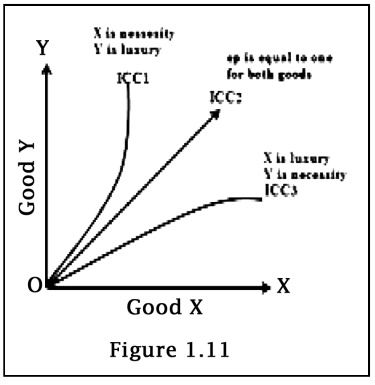

Figure 1.11

On the other hand, if the quantity purchased of a commodity increases more than proportionately to the increases in income, it is called a luxury. In figure 1.11, the slope of income consumption curve ICC_1 is increasing which implies that the quantity purchased of the commodity X increases less than proportionately to the increases in consumer's income. Therefore, in this case of ICC_1 good X is a necessity and good Y is luxury.

On the other hand, the slope of income consumption curve ICC_3 is decreasing which implies that the quantity purchased of good X increases more than proportionately to increases in income and therefore in this case good X is luxury and good Y is necessity. It will be seen from figure that the income consumption curve ICC_2 is a linear curve passing through the origin which implies that the increases in the quantities purchased of both the goods are rising in proportion to the increase in income and therefore neither good is a luxury or a necessity.

1.14. The Substitution Effect - Hicks

The substitution effect relates to the change in the quantity demanded resulting from a change in the price of good due to the substitution of relatively cheaper good for a dearer one, while keeping the price of the other good and real income and tastes of the consumer as constant. Prof. Hicks has explained the substitution effect independent of the income effect through compensating variation in income. "The substitution effect is the increase in the quantity bought as the price of the commodity falls, after adjusting income so as to keep the real purchasing power of the consumer the same as before. This adjustment in income is called compensating variations and is shown graphically by a parallel shift of the new budget line until it become tangent to the initial indifference curve."

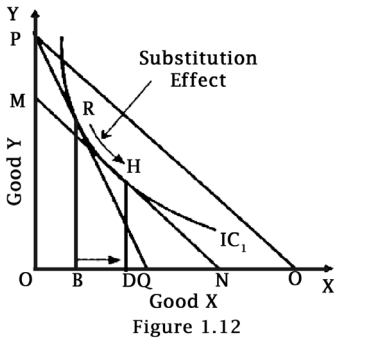

Figure 1.12

Thus on the basis of the methods of compensating variation, the substitution effect measure the effect of change in the relative price of a good with real income constant. The increase in the real income of the consumer as a result of fall in the price of, say good X, is so withdrawn that he is neither better off nor worse off than before.

The substitution effect is explained in Figure 1.12 where the original budget line

is PQ with equilibrium at point R on the indifference curve IC1. At R, the consumer is buying OB of X and BR of Y. Suppose the price of X falls so that his new budget line is PQ1. With the fall in the price of X, the real income of the consumer increases. To make the compensating variation in income or to keep the consumer's real income constant, take away the increase in his income equal to PM of good Y or Q1N of good X so that his budget line PQ1 shifts to the left as MN and is parallel to it. At the same time, MN is tangent to the original indifference curve lC1 but at point H where the consumer buys OD of X and DH of Y. Thus PM of Y or Q1N of X.

represents the compensating variation in income, as shown by the line MN being tangent to the curve IC1 at point H. Now the consumer substitutes X for Y and moves from point R to H or the horizontal distance from B to D. This movement is called the substitution effect. The substitution affect is always negative, the relation between price and quantity demanded being inverse, the substitution effect is negative.

1.15. Price Effect - Income and Substitution Effects - Hicks

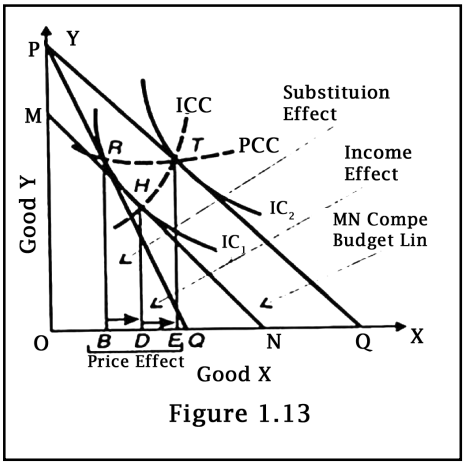

Figure 1.13

Hicks has separated the substitution effect and the income effect from the price effect through compensating variation in income by changing the relative price of a good while keeping the real income of the consumer constant. Suppose initially the consumer is in equilibrium at point R on the budget line PQ where the indifference curve IC_1, is tangent to it at point R in Figure 1.13.

Let the price of good X fall. As a result, his budget line rotates outward to PQ, where the consumer is in equilibrium at point T on the higher indifference curve IC_2.The movement from R to T or B to E on the horizontal axis is the price effect of the fall in the price of X. With the fall in the price of X, the consumer's real income increases. To make the compensating variation in income in order to isolate the substitution effect, the consumer's money income is reduced equivalent to PM of Y or Q_1N of X by drawing the budget line MN parallel to PQ_1, so that it is tangent to the original indifference curve IC_1 at point H.

The movement from R to H on the IC_1, curve is the substitution effect whereby the consumer increases his purchases of X from B to D on the horizontal axis by substituting X for Y because it is cheaper.

It may be noted that when there is a fall (or rise) in the price of good X, the substitution effect always leads to an
increase (or decrease) in its quantity demanded. Thus the relation between price and quantity demanded being inverse, the substitution effect of a price change is always negative, real income being held constant.

Short Type Questions :

1. Ordinal utility analysis
2. Budget line
3. Consumer equilibrium
4. Nudge theory
5. Substitution Effect
6. Indifference schedule
7. Network effects
8. Price consumption curve
9. Income consumption curve

Essay Type Questions :

1. Explain Origins and Principles of Nudge theory
2. Describe the Benefits, Ethical considerations and criticisms on Nudge theory
3. Bring out the Role of Artificial Intelligence in consumer Decision making
4. Explain Demand elasticity in Digital Markets
5. Explain Price effect into income and substitution effects with the help of diagram

2.8. Sustainable Production Method

2.9. Returns to Scale

2.10. Economies of Scale in Digital Market

2.11. Cob-Douglas Production Function

2.12. Role of Big data in Production Analysis

2.1 Production Function

The processes and methods used to transform tangible inputs (raw materials, semi- finished goods, subassemblies) and intangible inputs (ideas, information, knowledge) into goods or services. Resources are used in this process to create an output that is suitable for use or has exchange value.

Production function is the technological relationship between inputs and output in physical terms. It specifies the maximum quantity of a commodity that can be produced per unit of time with given quantities of inputs and technology. A production function may take the form of a schedule, a graphical line or curve, an algebraic equation or a mathematical model. The general form a production function may be algebraically expressed as:

Q = f (K, L, N, O)
Where Q = the quantity of output
K = capital, and
L = labour
N = Land
O = Organisation

2.2. Factors of Production

The **factors of production** are the basic resources used to produce goods and services. Economists generally recognize four main factors: land, labor, capital, and entrepreneurship. Each of these factors receives a specific type of payment in return for its use. Those who control the factors of production often enjoy the greatest wealth in a society. Under capitalism, the factors of production are most often controlled by business owners and investors. In socialist societies, the government exerts greater control over the factors of production.

The Four Factors of Production

1. **Land:** This factor includes all natural resources used in production. It is not just the physical ground, but also things that come from it, such as forests, minerals, water, and oil. The payment for using land is called rent.
2. **Labor**: This refers to the human effort, both physical and mental—that goes into creating goods and services. The value of labor can be influenced by a person's skills, education, and experience, which is often referred to as **human capital**. The payment for labor is **wages**.
3. **Capital**: This includes all the man-made goods used to produce other goods and services. This is not to be confused with money, but rather the tools, machinery, buildings, and technology used in the production process. The payment for capital is interest.
4. **Entrepreneurship**: This is the creative and managerial factor that combines the other three factors to create a product or service. Entrepreneurs take on the risks of starting a business, innovating, and bringing new ideas to the market. The payment for entrepreneurship is profit.

2.3 Short Run Production Function

The short run production function is one in which at least is one factor of production is thought to be fixed in supply, i.e. it cannot be increased or decreased, and the rest of the factors are variable in nature. In general, the firm's capital inputs are assumed as fixed, and the production level can be changed by changing the quantity of other inputs such as labour, raw material, labour and so on. Therefore, it is quite difficult for the firm to change the capital equipment, to increase the output produced, among all factors of production.

In such circumstances, the law of variable proportion operates, which states the consequences when extra units of a variable input are combined with a fixed input. In short run, increasing returns are due to the indivisibility of factors and specialization, whereas diminishing returns are due to the perfect elasticity of substitution of factors.

2.4. Law of Variable Proportions - Importance

The law of variable proportions states that as the quantity of one factor is increased, keeping the other factors fixed, the marginal product of that factor will eventually decline. This means that up to the use of a certain amount of variable factor, marginal product of the factor may increase and after a certain stage it starts diminishing. When the variable factor becomes relatively abundant, the marginal product may become negative.

Assumptions :

1. **Constant Technology:** The state of technology is assumed to be given and constant. If there is an improvement in technology the production function will move upward.
2. **Factor Proportions are Variable:** The law assumes that factor proportions are variable. If factors of production are to be combined in a fixed proportion, the law has no validity.
3. **Homogeneous Factor Units:** The units of variable factor are homogeneous. Each unit is identical in quality and amount with every other unit.
4. **Short-Run:** The law operates in the short-run when it is not possible to vary all factor inputs.

The law of variable proportion is illustrated in the following table 2.1 (A) and figure. 2.1(A). Suppose there is a given amount of land in which more and more labour (variable factor) is used to produce wheat. It can be seen from the table that up to the use of 3rd units of labour, total product increases at an increasing rate and beyond the 3rd unit total product increases at a diminishing rate. This fact is shown by the marginal product which addition is made to Total Product as a result of increasing the variable factor i.e. labour.

Units of Labour	Total Product	Average Product	Marginal Product
1	2	2	2
2	6	3	4
3	12	4	6
4	16	4	4
5	18	3.6	2
6	18	3	0
7	16	2.3	-2

Table 2.1 (A)

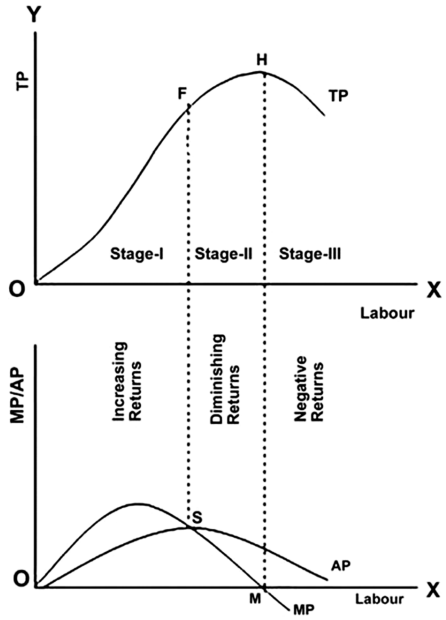

Figure 2.1 (A)

It can be seen from the table that the marginal product of labour initially rises and beyond the use of 3rd units of labour, it starts diminishing. The use of 6th units of labour does not add anything to the total production of wheat. Hence, the marginal product of labour has fallen to zero. Beyond the use of 6th units of labour, total product diminishes and therefore marginal product of labour becomes negative. Regarding the average product of labour, it rises up to the use of 3rd unit of labour and beyond that it is falling throughout.

Three Stages of the Law of Variable Proportions: These stages were illustrated in figure 2.1 (A) where labour is measured on the X-axis and output on the Y-axis.

1st Stage of Increasing Returns : In this stage, total product increases at an increasing rate up to a point. This is because the efficiency of the fixed factors increases as additional units of the variable factors are added to it. In the figure, from the origin to the point F, slope of the total product curve TP is increasing i.e. the curve TP is concave upwards upto the point F, which means that the marginal product MP of labour rises. The point F where the total product stops increasing at an increasing rate and starts increasing at a diminishing rate is called the point of inflection. Corresponding vertically to this point of inflection marginal product of labour is maximum, after which it diminishes. This stage is called the stage of increasing returns because the average product of the variable factor increases throughout this stage. This stage ends at the point where the average product curve reaches its highest point.

2nd Stage of Diminishing Returns : In this stage, total product continues to increase but at a diminishing rate until it reaches its maximum point H where the second stage ends. In this stage both the marginal product and average product of labour are diminishing but are positive. This is because the fixed factor becomes inadequate relative to the quantity of the variable factor. At the end of the second stage, i.e., at point M marginal product of labour is zero which corresponds to the maximum point H of the total product curve TP. This stage is important because the firm will seek to produce in this range.

3rd Stage of Negative Returns : In stage 3, total product declines and therefore the TP curve slopes downward. As a result, marginal product of labour is negative and the MP curve falls below the X-axis. In this stage the variable factor (labour) is too much relative to the fixed factor.

Importance of the Law of Variable Proportion:

The Law of Variable Proportion has universal applicability in any branch of production. It forms the basis of a number of doctrines in economics.

1. The Malthusian theory of population stems from the fact that food supply does not increase faster than the growth in population because of the operation of the law of diminishing returns in agriculture.
2. Ricardo also based his theory of rent on this principle. According to him rent arises because the operation of the law of diminishing return forces the application of additional doses of labour and capital on a piece of land.
3. The law of diminishing marginal utility and that of diminishing marginal physical productivity in the theory of distribution are also based on this theory.

2.5. Types of Automation

Automation can be categorized in a few different ways, but the most common classifications are based on the flexibility and complexity of the system. A traditional and widely used framework divides automation into three main types, particularly in a manufacturing context: fixed, programmable, and flexible.

1. Fixed Automation (Hard Automation): This type of automation is used for a fixed sequence of operations. The equipment is custom-designed and "hard-wired" for a specific product or task. It is not easily changed or reprogrammed.

Characteristics of Fixed Automation

1. High initial investment.
2. Very high production rates and low unit cost.
3. Inflexible to changes in product design.
4. Best suited for high-volume production of a single product with a long product life cycle.

Examples:

1. Automotive assembly lines for welding and painting.
2. Conveyor systems that move parts in a specific, unchangeable path.
3. Bottling plants and continuous chemical processing.

2. Programmable Automation: In this type, the production equipment can be reprogrammed to accommodate different products. However, the changeover process requires a period of downtime to load new programs and reconfigure the machinery.

Characteristics:

1. High initial investment in general-purpose equipment.
2. Lower production rates than fixed automation.
3. Suitable for batch production where product styles are changed occasionally.
4. Offers more flexibility than fixed automation.

Examples:

1. Computer Numerical Control (CNC) machine tools that can be programmed to cut different shapes.
2. Industrial robots that can be reprogrammed for different tasks, like welding or material handling for different products.

3. Flexible Automation (Soft Automation) : This is an extension of programmable automation where the system can be changed over from one product style to another with minimal or no downtime. The reprogramming and setup changes are done quickly and automatically, often without interrupting production.

Characteristics:

1. High initial investment in a highly integrated and sophisticated system.
2. Can produce a wide variety of products simultaneously or in a mixed-model format.
3. Offers the greatest flexibility in product design and production schedule.
4. Ideal for medium-volume production with a large variety of products.

Examples:

Flexible Manufacturing Systems (FMS) where a central computer controls a network of CNC machines, robots, and material handling systems to produce different parts on the same line.

In addition to these industrial classifications, other types of automation are often discussed in the context of business and IT:

1. **Process Automation**: Automating a series of tasks or an entire business process using software. This is often seen in workflow management and Robotic Process Automation (RPA).
2. **Intelligent Automation**: This combines traditional automation with artificial intelligence (AI), machine learning, and natural language processing to handle more complex, non-rule-based tasks that require cognitive skills.
3. **Integrated Automation**: A comprehensive system that automates all aspects of a manufacturing plant, from design to production, with minimal human intervention. This is also referred to as Computer-Integrated Manufacturing (CIM).

2.6. Role of Artificial Intelligence in promotion of Automation

Artificial Intelligence role is to make automation systems more intelligent, flexible, and capable of handling complex tasks that were once exclusively performed by humans. While traditional automation follows a rigid set of rules, Artificial Intelligence introduces cognitive abilities like learning, reasoning, and decision-making, transforming automation from a simple rule-based system into a dynamic and adaptive one.

Key Ways Artificial Intelligence Promotes Automation :

1. **Enabling Intelligent Decision-Making:** Traditional automation is limited to pre-programmed tasks. AI, particularly through machine learning (ML), allows automated systems to analyze large datasets, identify patterns, and make real-time decisions without human intervention. For example, an AI-powered system can predict equipment failure and schedule maintenance automatically, a process known as predictive maintenance.
2. **Handling Unstructured and Complex Data:** A major limitation of conventional automation is its inability to process unstructured data like images, speech, or handwritten text. AI, using technologies like computer vision and natural language processing (NLP), enables automated systems to understand and interact with this type of data. A robot on an assembly line can use computer vision to perform quality control by visually inspecting products for defects.
3. **Improving Flexibility and Adaptability:** AI allows automation to adapt to new or changing conditions. Instead of having to be completely reprogrammed for a new task, an AI-powered system can learn on the fly. This is particularly evident in robotic process automation (RPA), where AI-enabled bots can handle more variable and complex tasks than their rule-based predecessors. This flexibility makes automation viable for a wider range of industries and applications.
4. **Enhancing Human-Machine Collaboration:** AI is a key driver for the development of collaborative robots (cobots). These robots are designed to work safely alongside humans, taking over repetitive or physically demanding tasks while humans focus on more strategic work. AI allows cobots to perceive their environment, understand human gestures, and respond accordingly, creating a more seamless and safe collaborative workspace.
5. **Optimizing Processes:** AI-driven automation can continuously analyze and optimize processes. By collecting data from various sensors and systems, AI can identify inefficiencies and bottlenecks in a workflow, then automatically adjust parameters to improve speed, quality, and resource usage. This allows businesses to achieve a level of operational efficiency and agility that would be impossible with traditional, fixed automation.

2.7. Importance of AI and Automation in Production-Challenges

Artificial Intelligence and automation are transforming production by creating smarter and more efficient manufacturing environments. Their importance lies in several key areas:

1. **Increased Efficiency and Productivity**: Automated systems can work 24/7 without breaks, performing tasks faster and more accurately than humans. AI algorithms can optimize production workflows, predict bottlenecks, and manage resources more effectively, leading to significant increases in output and efficiency.
2. **Improved Quality Control**: AI-powered computer vision systems can perform real-time quality inspections with a level of precision that is impossible for human eyes. They can detect microscopic defects, ensuring that products consistently meet high-quality standards and reducing waste from faulty goods.
3. **Cost Reduction**: While the initial investment is high, automation and AI lead to long-term cost savings by reducing labor costs, minimizing material waste, and decreasing energy consumption.
4. **Enhanced Worker Safety**: Robots and automated systems can handle dangerous or repetitive tasks, such as lifting heavy objects, working with toxic chemicals, or operating in extreme temperatures. This protects human workers from injury and allows them to focus on more complex, strategic tasks.
5. **Greater Flexibility and Customization**: AI-driven automation enables **flexible manufacturing systems** that can be quickly reprogrammed to produce a variety of products. This agility allows companies to respond rapidly to changing market demands and consumer preferences for customized goods.

Challenges of AI and Automation in Production

1. High Initial Investment: The cost of purchasing and installing new machinery, software, and IT infrastructure can be prohibitively expensive, especially for small and medium-sized enterprises (SMEs). This significant upfront capital expenditure can be a major barrier to adoption.

2. Lack of a Skilled Workforce: A major challenge is the "skills gap." Businesses need specialized employees to design, operate, and maintain these sophisticated systems. Finding and retaining talent with expertise in robotics, data science, and AI is difficult and costly. Additionally, existing employees may require extensive **upskilling** or **reskilling** to adapt to new roles.

3. Integration with Legacy Systems: Many manufacturing companies operate with older, "legacy" equipment that is not designed to be compatible with modern AI and automation technologies. Integrating new systems with old ones can be complex, time-consuming, and require significant customization, which adds to the overall cost and risk.

4. Data Management and Quality: AI relies on large volumes of high-quality data to function effectively. Many companies lack a robust data collection and management infrastructure, and the data they do have may be inconsistent or incomplete, leading to unreliable AI outputs.

5. Cyber security Risks: As production systems become more interconnected and reliant on data, they become more vulnerable to cyber threats. A hack or data breach could lead to production shutdowns, intellectual property theft, or compromise sensitive data.

6. Ethical and Social Concerns: AI systems can inherit biases from their training data, leading to unfair or discriminatory outcomes. There are also unresolved questions of accountability, who is responsible when an autonomous AI system makes a mistake that leads to a negative outcome? The legal and regulatory frameworks for AI are still in their infancy, creating a climate of uncertainty.

2.8. Sustainable Production Method

A sustainable production method is a way of creating goods and services that minimizes negative environmental, social, and economic impacts throughout a product's entire life cycle, from sourcing raw materials to disposal. The goal is to meet the needs of the present without compromising the ability of future generations to meet their own. Sustainable production is a holistic approach that focuses on a few core areas.

1. Circular Economy Practices: The circular economy is a model that aims to eliminate waste and keep resources in use for as long as possible. Instead of the traditional "take-make-dispose" linear model, it focuses on the 9 R's: Rethink, Refuse, Reduce, Reuse, Repair, Refurbish, Remanufacture, Repurpose, and Recycle. This approach reduces the need for new raw materials and minimizes landfill waste.

2. Resource and Energy Efficiency: This involves using fewer resources and less energy to produce the same amount of output. Key strategies include:

1) **Renewable Energy:** Shifting from fossil fuels to renewable sources like solar, wind, and hydropower to power manufacturing operations.
2) **Lean Manufacturing:** A production method that focuses on eliminating waste in all its forms (e.g., wasted time, materials, and motion) to increase efficiency and reduce costs.
3) **Water Conservation:** Implementing technologies and processes that reduce water consumption and promote the reuse of wastewater.

3. **Sustainable Materials:** Choosing materials that have a lower environmental impact is crucial. This can include:

1) **Recycled Materials:** Using post-consumer or post-industrial waste as a raw material for new products.
2) **Bio-based Alternatives:** Utilizing materials derived from renewable biological resources, such as bioplastics from cornstarch instead of petroleum-based plastics.
3) **Ethical Sourcing:** Ensuring that raw materials are sourced responsibly, without causing harm to ecosystems or exploiting labor.

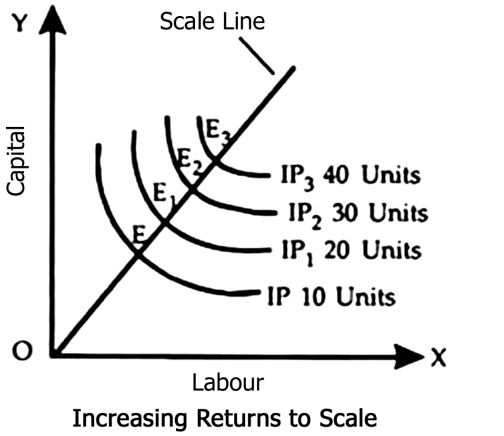
4. **Product Design:** Sustainable production begins at the design stage. By designing products for durability, reparability, and disassembly, companies can significantly extend a product's life and make it easier to recycle or reuse components at the end of its life. This also involves designing products with minimal and eco-friendly packaging.

2.9. Returns to Scale

The changes in output on account of the change in the factors of production in the same proportion are called the returns to scale. In the long run all the factors of production are variable and even the scale of production can be changed according to the demand for various goods and services in the economy. The returns to scale are concerned with long run production function. They are studied with the help of iso-product curves and iso- cost curves. Returns to scale are of three types as follows:

1. Increasing Returns to Scale : When the change in output is more than in proportion to the equi-proportional change in all the factors of production, then the operating law is called the increasing returns to scale. Thus, the rate of increase in output is faster than the increase in factors of production.

The distance between various iso-product curves decreases on the expansion path or scale line then the increasing returns to scale will operate. It reveals that the increase in output in the same proportion requires fewer ratios of labour and capital. Thus, output increases more than in proportion to the units of factors of production employed under this law. It can be explained with the help of Figure 2.2.



Increasing Returns to Scale

Figure 2.2

Capital and labour are shown on OY- axis and OX-axis respectively. IP, IP1, IP2 and IP3 are different iso-product curves showing different levels of output, viz., 10 units, 20 units, 30 units and 40 units. The distance between successive iso-product curves diminishes as output is expanded by increasing the scale. The distance $EE_1 > E_1E_2 > E_2E_3$ which reveals that for equal increase in output, firm has to employ less and less amount of labour and capital. The increasing returns to scale operate on account of the following causes or reasons:

1. **Indivisibilities of Inputs:** There are some factors of production which are indivisible. Indivisibility means that they are available in a given shape or they cannot be divided into small pieces. Machine, managers, research, finance and marketing are such examples of individualities. With the increase in the scale of production the efficiency increases and the output increases more than in proportion to the change in inputs.

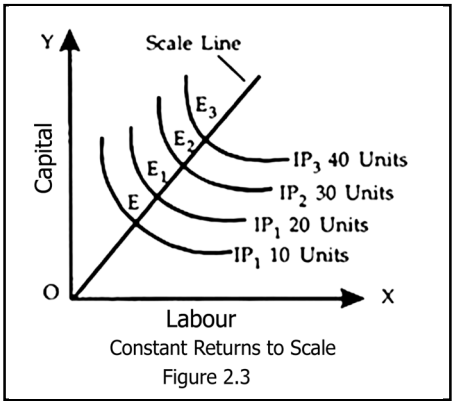
2. **Division of Labour and Specialisation:** When the scale of production is increased the division of labour and specialisation is introduced. A process of production is divided into sub-processes and each process is completed by each group of workers and at the same time the specialist are appointed for different departments, viz., finance manager, marketing manager, personnel manager, purchasing manager and so on and so forth. Their services lead to increase in the production and the increasing returns to scale operates.

3. **Dimensional Efficiency:** Increasing returns to scale is the result of operating dimensional efficiency in a business firm which is on account of the large size. The size increases the efficiency of all inputs and the increasing returns operates. Thus the investment in capital assets after a point will increase the output due to increased dimension of efficiency.

4. **Economies of Large Scale:** When the scale of production is increased the internal and external economies of scale will operate and on account of it the increasing returns to scale will also operate.

Internal economies are on account of firm's size and organisation while external economies are caused by the concentration and localisation of industries. All these economies lead to increase in output more than in proportion to the change in the ratio of two inputs.

2. Constant Returns to Scale : When the output of a firm increases in the same proportion in which the change in inputs takes place the law is called constant returns to scale. The proportion of two inputs remains constant. When all iso- product curves showing the same level of output have the equal distance between them on the expansion path or scale line, the law operating is called constant returns to scale. It is explained with the following figure 2.3



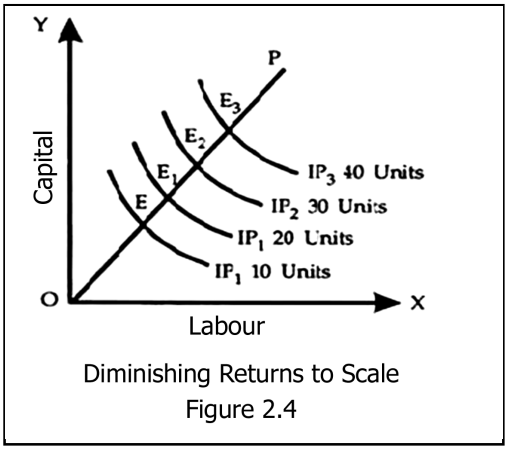
Constant Returns to Scale
Figure 2.3

Capital and labour are shown on OY - axis and OX-axis respectively. IP, IP1, IP2 and IP3 are different iso-product curves showing different levels of output, viz., 10 units, 20 units, 30 units and 40 units. The distance between iso-product curves is indicated by E, E_1, E_2 and E_3. The distance on scale line (OP) are equal.

$EE_1 = E_1E_2 = E_2E_3$. The distance between all iso-product curves remains constant which reveal that the production increases in the same proportion in which inputs are changed.

Hence, it is constant returns to scale. This law operates at the point where neither the internal and external economies nor internal and external diseconomies are enjoyed by the firm during long period.

3. **Diminishing Returns to Scale:** When proportionate change in output is less than the proportionate change in all the factors of production their (inputs) ratio being equal, the diminishing returns to scale will operate. The distance between various iso-product curves on the scale line increases because for getting the same level of output we have to employ more of all inputs. It is explained with the help of the following figure 2.4



Diminishing Returns to Scale
Figure 2.4

Labour and capital are employed on OX-axis an OY-axis. OP is the scale line on which E, E_1, E_2 and E_3 different iso-product curves are showing different levels of output. The distance between these curves are increasing on the scale line which show that we have to employ more of inputs and the resultant output is less than in proportion to the change in inputs. $EE_1 < E_1E_2 < E_2E_3$ which show the diminishing returns to scale.

2.10. Economies of Scale in Digital Market

Economies of scale refer to the cost advantages a company gains by producing a diverse range of products or services together, rather than separately. On digital platforms, this concept is amplified and profoundly impacts production efficiency. Digital platforms significantly impact economies and production efficiency by enabling businesses to streamline processes, reduce costs, and improve product quality.

Economies of Scale in Digital Platforms

Digital platforms are a fertile ground for economies of scale due to the nature of digital assets and the platform model itself. Unlike traditional production, which is often limited by physical constraints, digital platforms can easily leverage shared resources across multiple products and services. Here's how this plays out:

1. **Shared Infrastructure:** A core technological infrastructure, such as a cloud computing service, user authentication system, or data storage, can be used to support a variety of different applications, features, and services. The fixed cost of developing and maintaining this infrastructure is spread across all of the platform's offerings, significantly reducing the average cost per unit of each product.

2. **Data and Network Effects:** Digital platforms collect vast amounts of data on user behavior and preferences. This data is a shared resource that can be leveraged to improve multiple services. For example, a social media platform can use data from a user's interactions with

one feature (e.g., likes on posts) to better personalize advertisements or recommend content on another feature (e.g., a video feed). This creates a powerful feedback loop known as network effects, where the value of the platform increases as more users join and more data is generated.

3. **User Base and Cross-Selling:** A digital platform's large and engaged user base is another shared resource. Once a user is on the platform, it's often easier and cheaper to introduce them to a new service or product than it is to acquire a brand-new customer. Platforms like Amazon, which started as an online bookstore, can easily cross-sell a huge variety of products and services, from streaming video to cloud computing, to their existing customer base.

1. Complementary Products: Digital platforms often thrive by offering complementary products that enhance each other's value. For instance, an operating system and its app store create a synergistic ecosystem where the existence of a robust app library makes the operating system more appealing, and the large user base of the operating system attracts more developers to create apps.

Impact on Production Efficiency

Economies of scale directly boost production efficiency on digital platforms by:

1. **Reducing Costs:** By sharing fixed costs and resources (like technology, data, and marketing efforts), platforms can produce and deliver a wide array of products and services at a much lower average cost than if each were created independently. This cost reduction is a key driver of efficiency.

2. **Accelerating Innovation:** The modular and scalable nature of digital platforms allows for rapid experimentation and the launch of new products. A platform with a pre-existing user base and infrastructure can quickly deploy a new feature, gather user feedback, and iterate without the need for significant, new capital investment. This speeds up the innovation process and reduces the risk associated with new product development.

3. **Improving Resource Utilization:** Instead of having dedicated teams and resources for each product line, economies of scale allow platforms to efficiently utilize their talent, technology, and data across the entire organization. For instance, the same team of data scientists can work on algorithms for multiple services, maximizing their impact and reducing redundancy.

Increasing Agility: With a shared foundation, digital platforms can be more agile and responsive to market changes. They can easily add or remove services and adapt their offerings to meet evolving consumer demands without overhauling their entire system. This flexibility is a significant source of production efficiency in a fast-paced digital world.

2.11. Cob-Douglas Production Function

Charles W. Cobb and Paul H. Douglas studied the relationship of inputs and outputs and formed an empirical production function, popularly known as Cobb-Douglas production function. Originally, C-D production function applied not to the production process of an individual firm but to the whole of the manufacturing production. The Cobb-Douglas production function is expressed by

$Q = AL^{\alpha}K^{\beta}$

Where Q is output. L and K are inputs of labour and capital respectively. A, α and β are positive parameters where $\alpha > 0$, $\beta > 0$. The equation tells that output depends directly on L and K and that part of output which cannot be explained by L and K is explained by A which is the 'residual', often called technical change.

Properties of the Cobb-Douglas (C-D) Production Function :

1. Degree of Homogeneity: C-D production function is a homogeneous function, the degree of homogeneity of the function being a + b. For here we obtain

$$A (tL)^{\alpha} (tK)^{\beta} = t^{\alpha+\beta} A L^{\beta}K^{\beta} = t^{\alpha+\beta} Q$$

where t is a positive real number.

We obtain from that if L and K are increased by the factor t, Q would increase by the factor t^{a+b}. Also gives us that the condition for the C-D function to become homogeneous of degree one (or linearly homogeneous) is $\alpha + \beta = 1$.

In that case, would give us that if L and K are increased by the factor t, then Q would also increase by the factor t. If the C-D production function is homogeneous of any degree a + b as in and then may be called the generalized version of the C-D function.

2. Return of Scales : The returns to scale is measured by the sum of exponents of Cobb-Douglas production function i.e., $\alpha + \beta$

If $\alpha + \beta = 1$, returns to scale are constant.

If $\beta + \beta > 1$, returns to scale are increasing.

If $\alpha + \beta < 1$, returns to scale are decreasing.

3. Marginal Production of Labour and Capital: In the case of C-D production function, the AP_L and MP_L curves and the AP_K and MP_K curves, all would be downward sloping. That is, if the firm increases the use of one of the inputs, that of the other remaining unchanged, then the AP and the MP of the former input would decrease. Let us establish this property.

$$MP_L = \alpha A (K/L)^{1-\alpha} = \alpha AP_L$$

$$= MP_L < AP_L (\because 0 < \alpha < 1)$$

Similarly, we may establish that both AP_K and MP_K curves would be downward sloping and the MP_K curve would lie below the AP_K curve.

4. Elasticity of substitution : In the case of C-D production function, coefficient of partial elasticity of Q w.r.t. a change in L, K remaining constant, would be $E^Q_L = a$ = constant, and the coefficient of partial elasticity of Q w.r.t. a change in K, L remaining constant, would be $E^Q = 1 - \alpha$ = constant. We may establish this property in the following way By definition, we have

$$E^Q_L = \frac{\partial Q/Q}{\partial L/L} = \frac{L}{Q} \cdot \frac{\partial Q}{\partial L} \quad \text{and} \quad E^Q_K = \frac{\partial Q/Q}{\partial K/K} = \frac{K}{Q} \cdot \frac{\partial Q}{\partial K}$$

5. Mariginal Rate of Technical Substitution : We have obtained both MP_L and MP_K to be functions of L-K ratio, this function have the following property also :

$MRTS_{L.K} = MP_L/MP_K$ = function of L/K ratio.

As we know, $MRTS_{LK}$ is the marginal rate of technical substitution of L for K.

$MP_L = \partial Q/\partial L$

$MP_K = \partial Q/\partial K$

$$MRTS_{LK} = \frac{MP_L}{MP_K} = \frac{\partial Q/\partial L}{\partial Q/\partial K} = \frac{\partial Q}{\partial L} \times \frac{\partial K}{\partial Q} = \frac{-\partial K}{\partial L}$$

2.12. Role of Big data in Production Analysis

Big data plays a pivotal and transformative role in production analysis, moving it from a reactive, historical-based approach to a proactive, predictive one. By collecting and analyzing vast amounts of information from sensors, machinery, enterprise systems, and the supply chain, companies can gain unprecedented insights that optimize every stage of the production lifecycle.

Here are the key roles of big data in production analysis:

1. **Real-time Process Optimization and Efficiency:** Big data allows for the continuous, real-time monitoring of the entire production floor. By integrating data from Internet of Things (IoT) sensors on machinery, robots, and assembly lines, companies can get a live and comprehensive view of their operations. This capability enables:

1) **Predictive Maintenance:** Analyzing data from machine sensors helps to identify patterns that indicate an impending failure. This allows maintenance to be scheduled proactively, preventing costly and unplanned downtime and extending the lifespan of equipment.

2) **Bottleneck Identification:** Big data analytics can pinpoint and visualize bottlenecks in the production flow as they happen, allowing managers to immediately address inefficiencies and reallocate resources to maintain a smooth and continuous process.

3) **Energy Consumption Analysis:** By analyzing energy usage data in real-time, companies can identify opportunities for conservation and optimize the power consumption of their machinery, leading to significant cost savings.

2. Enhanced Quality Control and Assurance: Big data provides a powerful and granular tool for ensuring product quality and consistency, moving beyond traditional sample-based testing.

1) **Real-time Defect Detection:** Machine vision systems and sensors on the production line can collect millions of data points and images of products. Big data analytics, often powered by machine learning algorithms, can instantly detect even minor defects or deviations from quality standards, flagging faulty products for immediate removal.

2) **Root Cause Analysis:** By correlating product quality data with production variables (e.g., machine settings, raw material batches, environmental conditions), big data can identify the root causes of recurring quality issues. This allows companies to implement permanent process improvements rather than just addressing symptoms.

3) **Supplier Quality Monitoring:** Data from incoming raw materials can be analyzed to assess supplier quality over time, ensuring a consistent and high standard of inputs for the production process.

3. Supply Chain Optimization and Demand Forecasting: The role of big data extends beyond the factory floor to the broader supply chain, providing a holistic view that improves decision-making and resilience.

1) **Accurate Demand Forecasting:** By analyzing historical sales data, market trends, customer feedback, and even external factors like weather and economic indicators, big data can generate highly accurate demand forecasts. This helps prevent both overproduction and inventory shortages, optimizing resource allocation.

2) **Supply Chain Visibility:** Big data platforms can integrate information from suppliers, logistics partners, and internal systems to provide end-to-end visibility. This allows companies to anticipate potential disruptions (e.g., a shipping delay) and take proactive measures.

3) **Inventory Management:** With better demand forecasting, companies can optimize inventory levels, reducing carrying costs and minimizing the risk of stockouts.

4. Strategic Decision-Making: Big data moves production analysis from a tactical level to a strategic one, providing actionable insights for top-level decision-makers.

1) **Performance Benchmarking:** Companies can use big data to benchmark their production performance against industry standards and their own historical data, identifying areas for improvement.

2) **What-if Scenario Analysis:** Advanced analytics can simulate the impact of changes to the production line, such as adding a new machine or altering a process. This allows managers to test potential strategies in a virtual environment before committing resources.

3) **Continuous Improvement and Innovation:** By constantly analyzing production data, companies can identify opportunities for small, continuous improvements, fostering a culture of innovation and efficiency.

Short Type Questions :

1. Production Function
2. Factors of Production
3. Short-run Production Function,
4. Sustainable Production Method
5. Types of Automation

Essay Type Questions :

1. Explain Law of Variable Proportions with the help og diagram
2. Describe the Role of AI in promotion of Automation
3. Bring out the Importance of AI and Automation in Production
4. Explain Returns to Scale
5. Write note on Scope of Economies in Digital Platforms and Production Efficiency
6. Describe the Cob-Douglas Production Function
7. Explain the Role of Big data in Production Analysis

3.1 Cost Concepts

Cost has been defined by the Committee on Cost Terminology of the American Accounting Association as "the foregoing, in monetary terms, incurred or potentially to be incurred in the realisation of the objective of management which may be manufacturing of a product or rendering of a service."

From the above, it may be stated that cost means the total of all expenses incurred for a product or a service. Thus, cost of an article means the actual outgoings or ascertained changes incurred in its production and sale activities. In short, it is the amount of resources used up in exchange for some goods or services.

1. Accounting costs: Accounting costs are those for which the entrepreneur pays direct cash for procuring resources for production. These include costs of the price paid for raw materials and machines, wages paid to workers, electricity charges, the cost incurred in hiring or purchasing a building or plot, etc. Accounting costs are treated as expenses. Chartered accountants record them in financial statements.

2. Real Cost: The real cost of production has been variously interpreted. Adam Smith regarded pains and sacrifices of labour as real cost of production. Marshall included under it the "real cost of efforts of various qualities", and "real cost of waiting." This Marshall called as the social cost of production.

3. Opportunity Cost: In modern economic analysis, the term real cost is interpreted in the sense of opportunity cost. It is also called 'alternative cost' or 'transfer cost'. Opportunity cost of a commodity is the alternative sacrificed in order to obtain it. Since productive resources are limited, if they are used in the production of one commodity, they are not available for the production of another. The commodity which is sacrificed or not produced is the real cost of the commodity that is produced. Thus, the cost of production, in the sense of opportunity cost, means not the efforts and sacrifices undergone, but the most attractive alternative foregone or the next best choice sacrificed.

4. Explicit Costs and Implicit Costs: Costs of production can be classified as Explicit Costs and Implicit Costs. Explicit costs are also called paid-out costs. These costs the entrepreneur has to pay to those persons from whom he has obtained factors of production or services. For instance, he has to pay wages to the labour he has employed, interest on the capital that he has borrowed and rent of land or factory or business premises. These are explicit costs. Implicit costs, on the other hand, are costs which have not to be paid out to others but the costs which the entrepreneur pays to himself, as it were. Perhaps he himself

is the owner of the business premises, he may have invested his own capital side by side the capital he may have borrowed from others. He may be a whole-time worker in the business, for instance he may be a managing director for which he may not be drawing any salary. If he had lent out these factors to others, he would have received remuneration from them. Hence they must be taken into account while calculating profit. But since they are not actually paid out to anybody, they are called implicit costs.

3.2 Short Run Costs and Cost Curves

Conceptually, in the short run, the quantity of at least one input is fixed and the quantities of the other inputs can be varied. In the short-run period, factors, such as land and machinery, remain the same. On the other hand, factors, such as labor and capital, vary with time. In the short run, the expansion is done by hiring more labor and increasing capital. The existing size of the plant or building cannot be increased in case of the short run. Following are the cost concepts that are taken into consideration in the short run:

1. Total Fixed Costs (TFC): Refer to the costs that remain fixed in the short period.

These costs do not change with the change in the level of output. For example, rents, interest, and salaries. In the words of Ferguson, "Total fixed cost is the sum of the 'short run explicit fixed costs and implicit costs incurred by the entrepreneur." Fixed costs have implication even when the production of an organization is zero. These costs are also called supplementary costs, indirect costs, overhead costs, historical costs, and unavoidable costs.

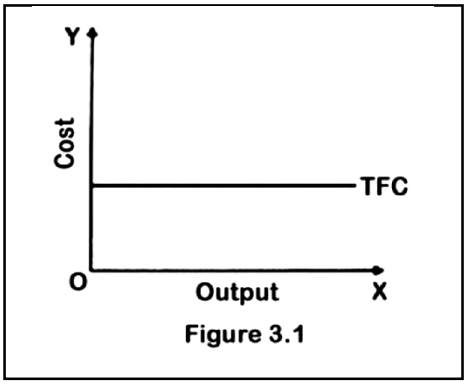

Figure 3.1

TFC remains constant with respect to change in the level of output. Therefore, the slope of TFC curve is a horizontal straight line. As shown in Figure 3.1, TFC curve is horizontal to x- axis. From Figure-3.1 it can be seen that TFC remains the same at all the levels with respect to change in the level of output.

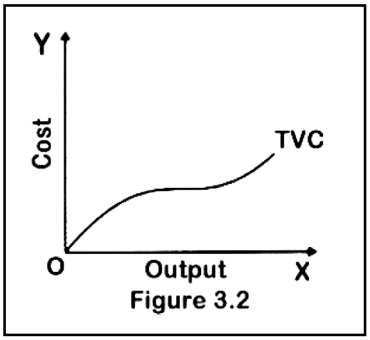

Figure 3.2

2. Total Variable Costs (TVC) : Refer to costs that change with the change in the level of production. For example, costs incurred on purchasing raw material, hiring labor, and using electricity. According to Ferguson, "total variable cost is the sum of amounts spent for each of the variable inputs used" If the output is zero, then the variable cost is also zero. These costs are also called prime costs, direct costs, and avoidable costs. In Figure 3.2 it can be seen that TVC curve changes with the change in the level of output.

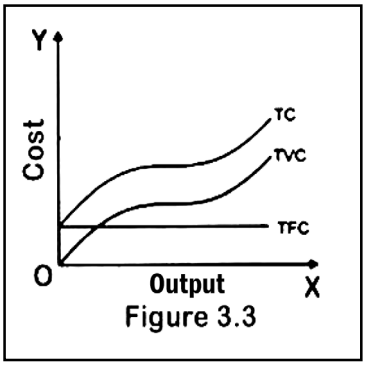

Figure 3.3

3. Total Cost (TC) : Involves the sum of TFC and TVC. It can be calculated as follows: Total Cost = TFC + TVC. TC also changes with the changes in the level of output as there is a change in TVC. Figure 3.3 shows the total cost curve derived from sum of TVC and TFC: It should be noted that both TVC and TC increase initially at decreasing rate and then they increase at increasing rate. Here decreasing rate implies that the rate at which cost increases with respect to output is less, whereas increasing rate implies the rate at which cost increases with respect to output is more.

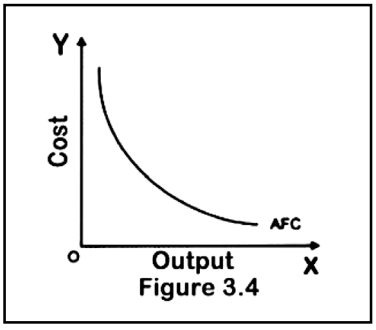

Figure 3.4

4. Average Fixed Costs (AFC) : Refers to the per unit fixed costs of production. In other words, AFC implies fixed cost of production divided by the quantity of output produced. It is calculated as: AFC = TFC/Output.

TFC is constant as production increases, thus AFC falls. Figure 3.4 shows the AFC curve. In Figure 3.4 AFC curve is shown as a declining curve, which never touches the horizontal axis. This is because fixed cost can never be zero. The curve is also called rectangular hyperbola, which represents that total fixed costs remain same at all the levels.

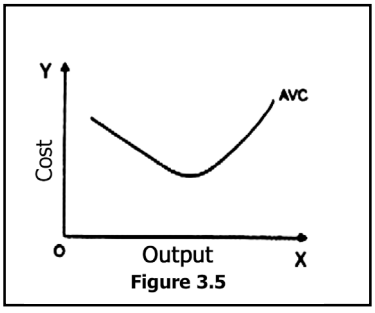

Figure 3.5

5. Average Variable Costs (AVC) : Refer to the per unit variable cost of production. It implies organization's variable costs divided by the quantity of output produced. It is calculated as:

AVC = TVC/ Output

Initially, AVC decreases as output increases. After a certain point of time, AVC ncreases with respect to increase in output. Thus, it is a U- shaped curve, as shown in Figure 3.5

6. Average Cost (AC): Refer to the total costs of production per unit of output. AC is calculated as: AC = TC/ Output AC is also equal to the sum total of AFC and AVC. AC curve is also U-shaped curve as average cost initially decreases when output increases and then increases when output increases. Figure 3.6 shows the AC curve.

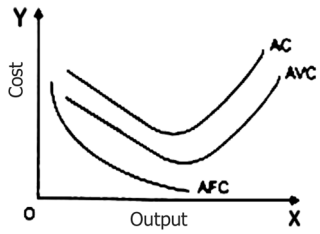

Figure 3.6

7. Marginal Cost: Refer to the addition to the total cost for producing an additional unit of the product. Marginal cost is calculated as: $MC = TC_n = TC_{n-1}$

n = Number of units produced It is also calculated as: MC = DTC / DQ

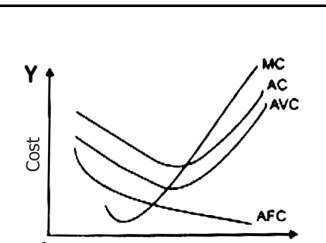

Figure 3.7

MC curve is also a U-shaped curve as marginal cost initially decreases as output increases and afterwards, rises as output increases. This is because TC increases at decreasing rate and then increases at increasing rate. Figure 3.7 shows the MC curve.

Let us learn the aforementioned cost concepts numerically with the help of Table: 3.1

Table 3.1

Output 0	TFC	TVC	TC TFC+TVC	AFC TFC / Q	AVC TVC / Q	AC TC / Q	MC
0	30	0	30	0	0	0	0
1	30	10	40	30	10	40	10
2	30	18	48	15	09	24	08
3	30	24	54	30	08	18	06
4	30	32	62	7.5	08	15.5	08
5	30	42	72	06	08	14.5	10
6	30	54	84	05	09	14	12
7	30	68	98	4.3	9.7	14	14
8	30	84	114	3.75	10.5	14.25	16

3.3. The Relation between the Average and Marginal Cost Curve

The relationship between the marginal cost and average cost is the same as that between any other marginal-average quantities. When marginal cost is less than average cost, average cost falls and when marginal cost is greater than average cost, average cost rises.

The relationship between average and marginal cost can be easily understood with the help of Figure 3.8, where short-run average cost curve AC and marginal cost curve MC are drawn. As long as short-run marginal cost curve MC lies below short-run average cost curve, the average cost curve AC is falling. When marginal cost curve MC lies above the average cost curve AC, the latter is rising.

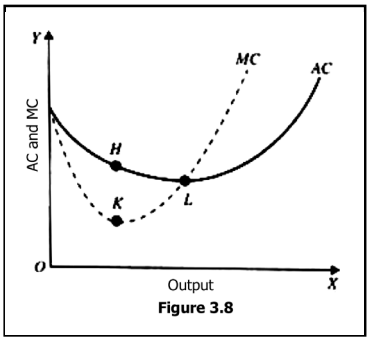

Figure 3.8

At the point of intersection L where MC is equal to AC, AC is neither falling nor rising, that is, at point L, AC has just ceased to fall but has not yet begun to rise. It follows that point L, at which the MC curve crosses the AC curve to lie above the AC curve is the minimum point of the AC curve. Thus, marginal cost curve cuts the average cost curve at the latter's minimum point. It is important to note that we cannot generalise about the direction in which marginal cost is moving from the way average cost is changing, that is, when average cost is falling we cannot say that marginal cost will be falling too. When average cost is falling, what we can say definitely is only that the marginal cost will be below it but the marginal cost itself may be either rising or falling.

Likewise, when average cost is rising, we cannot deduce that marginal cost will be rising too. When average cost is rising, the marginal cost must be above it but the marginal cost itself may be either rising or falling. Consider Fig.3.8 where up to the point K, marginal cost is falling as well as below the average cost.

But beyond point K and up to point L marginal cost curve lies below the average cost curve with the result that the average cost curve is falling. But it will seen that between K and L where the marginal cost is rising, the average cost is falling. This is because though MC is rising between K and L, it is below AC. It is therefore clear that when the average cost is falling, marginal cost may be falling or rising.

3.4. Long Run Average Cost (LAC) Curve

Long run is that time period when a firm can change all its inputs. In fact, there are no fixed inputs in the long run; all inputs are variable. Thus, in the long run, there is no fixed cost; all costs are variable. That is why, in the long run, a firm can change its scale of production according to its needs.

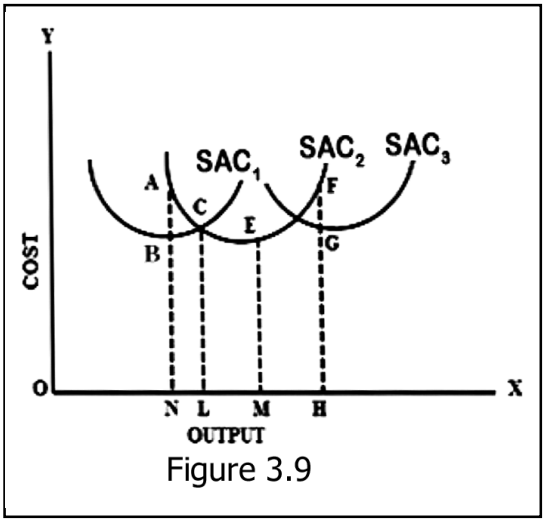

Figure 3.9

In the short run, size of a plant or the scale remains fixed while, in the long run, changes in plant size can be made. In the long run, a firm can move from one plant to another plant thereby giving rise to different cost relationships. If the situation demands, it can build up a large- sized plant or a smaller one.

Suppose the demand for the firm's product has increased. To meet this firm can expand the existing plant or install new ones. Each plant is suitable for a particular range of output. The firm will therefore make use of the various plants up to that level where the average cost fall with increase in output. It will not produce beyond the minimum average cost of producing various outputs from all the plants used together.

In the figure 3.9 there are three plants represented by their average cost curves SAC1, SAC2, SAC3. Each curve represents the scale of the firm. SAC1 depicts is lower scale while the movement from SAC1, SAC2, shows the firm to be a large size. For producing ON output, the firm can se SAC1 or SAC2 plant.

The firm will, however, use the scale of plant represented by SAC1 since the average cost of production ON output is NB which is less than NA, the cost of producing this output on the SAC2. If the firm is to produce OL output, it would produce at either of the two plants. But it would be advantageous for the firm to use the plant SAC2 for OL level of output because the larger output OM can be obtained at the lowest average cost ME from this plant. However, for output OH, the firm would use the SAC3 plant where the average cost HG

is lower than HF of the SAC2 plant. Thus in the long-run in order to produce any level of output the firm will use that plant which has the minimum unit cost.

But in the log-run average cost curve LAC is usually shown as a smooth curve fitted to the SAC curves so that it is tangent to each of them at some point However, let us assume that the industry faces a large number of plant sizes represented by, say, five SAC curves, as shown in Fig. 3.10. These curves will generate a smooth and continuous curve called the 'planning curve' or the LAC curve.

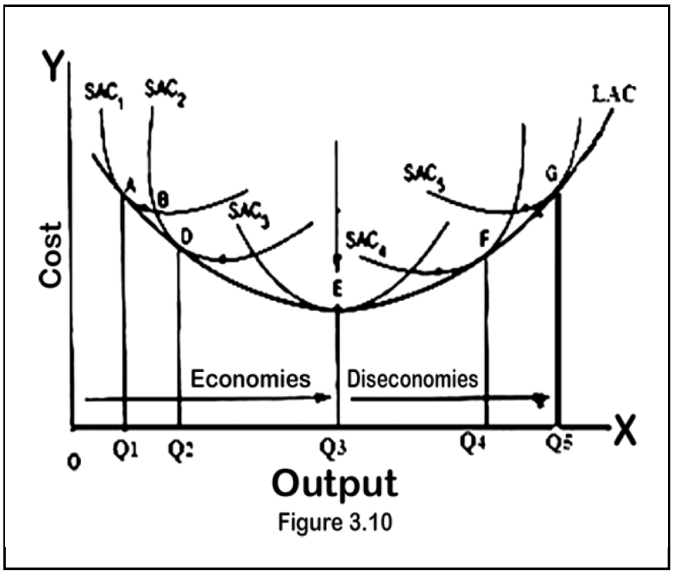

Figure 3.10

Each point on this curve shows the least possible cost for producing the corresponding level of output. The LAC curve is a planning curve because it is the curve which helps a firm to decide which plant is to be established in order to produce an output level consistent with the optimal cost.

The firm selects that short run plant which yields the minimum cost of producing the anticipated output level. To produce a particular output in the long run, the firm must select a point on the LAC curve corresponding to that output, and it will then build a relevant short run plant and operate on the corresponding SAC curve. This was shown at point E on plant SAC_3

3.5. Economies of Scale

Economies of scale are cost reductions that occur when companies increase production. The fixed costs, like administration, are spread over more units of production. Sometimes the company can negotiate to lower its variable costs as well. Economies of scale not only benefit the organization. Consumers can enjoy lower prices. The economy grows as lower prices stimulate increased demand. Economies of scale give a competitive advantage to large entities over smaller ones. The larger the business, non-profit, or government, the lower its per-unit costs.

There are two main types of economies of scale : internal and external. Internal economies are controllable by management because they are internal to the company. External economies depend upon external factors. These factors include the industry, geographic location, or government.

I. Internal Economies of Scale: Internal economies result from a larger volume of production. For example, large companies have the ability to buy in bulk. This lowers the cost per unit of the materials they need to make their products. As a firm expands its scale of operations, it is said to move into its long run. The benefits arising from expansion depend upon the effect of expansion on productive efficiency, which can be assessed by looking at changes in average costs at each stage of production. A firm can increase its scale of operations in two ways.

1. Internal growth, also called organic growth
2. External growth, also called integration - by merging with other firms, or by acquiring other firms.

There are five main types of internal economies of scale.

1. Technical Economies: Technical economies are the cost savings a firm makes as it grows larger, and arise from the increased use of large scale mechanical processes and machinery. For example, a mass producer of motor vehicles can benefit from technical economies because it can employ mass production techniques and benefit from specialisation and a division of labour.

2. Marketing or Purchasing Economies: Purchasing economies are gained when larger firms buy in bulk and achieve purchasing discounts. For example, a large supermarket chain can buy its fresh fruit in much greater quantities than a small fruit and vegetable supplier.

3. Administrative Economies: Administrative savings can arise when large firms spread their administrative and management costs across all their plants, departments, divisions, or subsidiaries. For example, a large multi-national can employ one set of financial accountants for all its separate businesses.

4. Financial Economies: Large firms can gain financial savings because they can usually borrow money more cheaply than small firms. This is because they usually have more valuable assets which can be used as security (collateral), and are seen to be a lower risk, especially in comparison with new businesses.

5. Risk bearing Economies: Risk bearing economies are often derived by large firms who can bear business risks more effectively than smaller firms. For example, a large record company can more easily bear the risk of a 'flop' than a smaller record label.

II. External Economies: External economies refer to all those benefits which accrue to all the firms operating in a given industry. Generally, these economies accrue due to the expansion of industry and other facilities expanded by the government. In the opinion of Prof. Chapman, 'The external economies are those in which all business firms in an industry can share". Prof. Cairn Cross has divided the external economies into three parts, as:

1. Economies of Concentration: As the number of firms in an area increases, each firm enjoys some benefits like, transport and communication, availability of raw materials, research and invention etc. Further, financial assistance from banks and non-bank institutions easily accrue to firms. We can therefore conclude that concentration of industries lead to economies of concentration.

2. Economies of Information: When the number of firms in an industry expands they become mutually dependent on each other. In other words, they do not feel the need of independent research on individual basis. Many scientific and trade journals are published. These journals provide information to all the firms, which relate to new market, sources of raw materials, latest techniques of production etc.

3. Economies of Disintegration: As the industry develops, all the firms engaged in it decide to divide and sub-divide the process. For instance, in case of moped industry, some firms specialize in rims, hubs and still others in chains, pedals, tyres etc.

It is of two types: (i) Horizontal - disintegration (ii) Vertical - disintegration.

In case of horizontal disintegration each firm in the industry tries to specialize in one particular item whereas, under vertical disintegration every firm endeavors to specialize in different types of items.

3.6. Digital and Technological Economies

The digital and technological economies are distinct but interconnected concepts. The technological economy refers to the technology sector itself, the industries that create, research, and develop technologically-based goods and services. The digital economy is a broader, more encompassing term that describes how all economic activities are being transformed by digital technologies.

Technological Economy: The technological economy, often called the "tech sector," is a specific industry within the larger economy. It includes companies that produce software, hardware, electronics, and provide IT services. These are the companies that create the tools and platforms that the digital economy uses. Technological Economy characteristics are as follows:

1. Focus on production: The primary activity is the creation and sale of technology. Think of companies that make computers, develop software, or provide cloud computing services.

2. High investment in R&D: These companies heavily invest in research and development to create new, innovative products and services.

3. Risk-oriented: The industry often takes on riskier projects with the potential for significant future growth. **Examples:** Companies like Apple, Google, and Microsoft.

Digital Economy: The digital economy is a pervasive force that has transformed how businesses operate and how consumers interact with the economy. It's not a single sector but rather the economic activity that results from the widespread use of digital technologies. This includes everything from e-commerce and online banking to the use of data analytics to improve traditional manufacturing processes. The digital economy characteristics are as follows:

1. **Pervasive transformation :** It's about how digital tools and platforms, created by the technological economy, are integrated into all sectors, including healthcare, finance, retail, and agriculture.
2. **Hyper connectivity :** The foundation of the digital economy is the growing interconnectedness of people, organizations, and machines through the internet, mobile technology, and the Internet of Things (IoT).
3. **Data-driven :** The digital economy leverages vast amounts of data to drive decision-making, personalize customer experiences, and create value.

   Examples : A local bakery using social media to market products and offering online ordering, or a traditional bank offering online and mobile banking services.

Relationship between Technological Economy and Digital Economy

Think of the technological economy as the engine and the digital economy as the road. The tech sector builds the cars (software, devices, etc.), and the digital economy is the collective activity that takes place on the roads they've created (e-commerce, remote work, online services). The technological economy provides the essential infrastructure and tools (like AI, cloud computing, and IoT) that enable the digital economy to flourish. The digital economy, in turn, creates a massive market for the products and services of the tech sector, driving its growth and innovation. They are deeply interdependent, with each fueling the expansion of the other.

3.7. Concepts of Revenue

The term revenue refers to the income obtained by a firm through the sale of goods at different prices. In the words of Dooley, 'the revenue of a firm is its sales, receipts or income'. The revenue concepts are concerned with Total Revenue, Average Revenue and Marginal Revenue.

1. Total Revenue: The income earned by a seller or producer after selling the output is called the total revenue. In fact, total revenue is the multiple of price and output. The behavior of total revenue depends on the market where the firm produces or sells.

Thus,

Where TR = AR X Q

TR = Total Revenue

AR = Average Revenue or Price per unit

Q = Output

For exmple if the price of a commodity is Rs. 100 and Total unit sold are 20 in that case total revenue will be

TR = 100 X 20 = 2000

TR = 2000

2. **Average Revenue:** Average revenue refers to the revenue obtained by the seller by selling the per unit commodity. It is obtained by dividing the total revenue by total output. "The average revenue curve shows that the price of the firm's product is the same at each level of output." Stonier and Hague

Thus :

AR = TR/Q

AR = Average Revenue

TR = Total Revenue

Q = Output

According to McDonnell, " Average Revenue is the per unit revenue recived from the sale of one unit of a Commodity."

TR = Price x Output

TR = P x Q

AR = PQ /Q = P

and P = f (Q) is an average curve which shows that price is a function of quantity demanded it is also a demand curve.

3. Marginal Revenue: Marginal revenue is the net revenue obtained by selling an additional unit of the commodity. "Marginal revenue is the change in total revenue which results from the sale of one more unit of output." Ferguson. Thus, marginal revenue is the addition made to the total revenue by selling one more unit of the good. In algebraic terms, marginal revenue is the net addition to the total revenue by selling n units of a commodity instead of n-1.

Therefore,

$MR = \Delta TR / \Delta MR_n = TR_n - TR_{n-1}$

Whereas TR_n = Total Revenue of 'n' units

TR_{n-1} = Total Revenue from (n-1) units MR_{n-1} = Marginal Revenue from nth unit

n = any given number

" The marginal revenue is the change in total revenue resulting from selling an additional unit of the commodity "

If total revenue from n units is 110 and from (n - 1) units is 100. in that case

MRnth = TRn - TRn -1 = 110 - 100

MRnth = 10

MR in mathematical terms is the ratio of change in total revenue to change in output

$MR = \Delta TR / \Delta Q$

3.8. Relationship - AR and MR in Perfect Competition Market

Revenue is the amount received by an organisation from the sale of a given quantity of a commodity in the market. There are three important terms in Revenue; viz., Total Revenue, Average Revenue, and Marginal Revenue. The total receipts from the sale of a given quantity of a commodity are known as Total Revenue. The revenue per unit of the output sold of a commodity is known as Average Revenue. The additional revenue generated by selling an additional unit of output is known as Marginal Revenue.

In markets like perfect competition, the price of a commodity remains constant at all levels of output and any firm in the industry cannot influence the market price. The sale of the product can be higher or lower at the same price only. This implies that the sale of any additional unit (MR) will be the same as AR. As a result, both AR and MR curves coincide in a horizontal straight line parallel to the X-axis. The relation of total revenue, average revenue and marginal revenue in perfect competition can be explained with the help of table 3.2 and fig 3.11.

Units Sold	Price/AR (₹)	TR (₹)	MR (₹)
1	10	10	10
2	10	20	10
3	10	30	10
4	10	40	10
5	10	50	10

Table 3.2

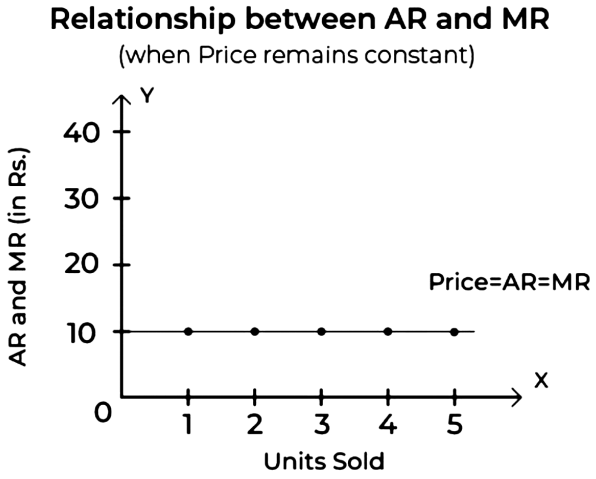

Figure 3.11

3.9. Relationship - AR and MR in Imperfect Competition Market

The relation of total revenue, average revenue and marginal revenue in imperfect competition can be explained with the help of table 3.3 and fig 3.12. The relationship between TR, AR and MR can be expressed with the help of a table 3.3 From the table 3.3 we can draw the idea that as the price falls from Rs. 10 to Rs. 1, the output sold increases from 1 to 10. Total revenue increases from 10 to 30, at 5 units. However, at 6th unit it becomes constant and ultimately starts falling at next unit i.e. 7th. In the same way, when AR falls, MR falls more and becomes zero at 6th unit and then negative. Therefore, it is clear that when AR falls, MR also falls more than that of AR: TR increases initially at a diminishing rate, it reaches maximum and then starts falling.

Table 3.3

Units Q	TR/Q = AR=P	P.Q = TR	(TRn - TRn-1) = MR
1	10	10	10
2	9	18	8
3	8	24	6
4	7	28	4
5	6	30	2
6	5	30	0
7	4	28	– 2
8	3	24	– 4
9	2	18	– 6
10	1	10	– 8

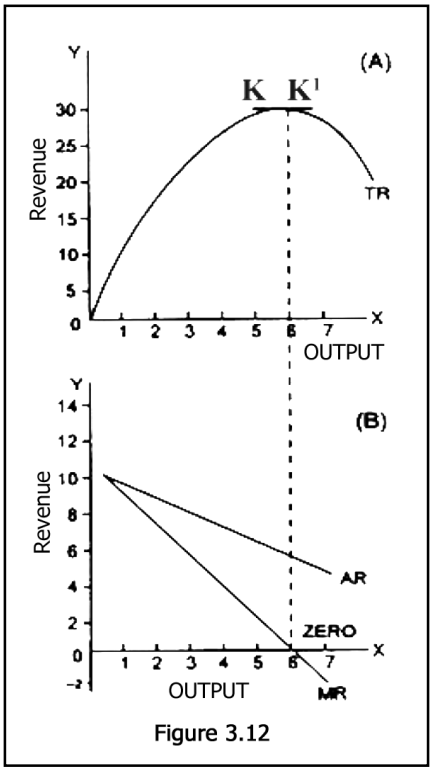

Figure 3.12

In figure 3.12 three concepts of revenue have been explained. The units of output have been shown on horizontal axis while revenue on vertical axis. Here TR, AR, MR are

total revenue, average revenue and marginal revenue curves respectively.

In figure 3.12 (A), a total revenue curve is sloping upward from the origin to point K. From point K to K1 total revenue is constant. But at point K1 total revenue is maximum and begins to fall. It means even by selling more units total revenue is falling. In such a situation, marginal revenue becomes negative.

Similarly, in the figure 3.12 (B) average revenue curves are sloping downward. It means average revenue falls as more and more units are sold. In fig. 3.12 (B) MR is the marginal revenue curve which slopes downward. It signifies the fact that MR with the sale of every additional unit tends to diminish. Moreover, it is also clear from the fig. that when both AR and MR are falling, MR is less than AR. MR can be zero, positive or negative but AR is always positive.

3.10. Subscription Model - Advantages and Disadvantages

A subscription model is a business strategy where customers pay a recurring fee at regular intervals (e.g., monthly, quarterly, or annually) to gain access to a product or service. This model has become everywhere across various industries, from software and streaming services to physical goods and media.

Advantages of the Subscription Model - For Businesses :

1. **Predictable and Recurring Revenue:** This is a major benefit. Unlike a one-time purchase, subscriptions create a steady and predictable stream of income. This stability allows companies to forecast revenue more accurately, manage cash flow, and plan for future investments and growth.
2. **Increased Customer Lifetime Value (CLV**): By retaining customers over a long period, businesses can significantly increase the total revenue they generate from each customer. The focus shifts from a single transaction to a long-term relationship.
3. **Enhanced Customer Loyalty and Retention:** The ongoing nature of the subscription model fosters a deeper relationship with customers. Businesses can engage with subscribers, gather feedback, and continuously improve their offerings, which in turn builds loyalty and reduces the rate of customer churn.
4. **Data-Driven Insights:** A continuous relationship provides a wealth of data on customer behavior, preferences, and usage patterns. This information is invaluable for personalizing services, developing new products, and optimizing marketing strategies.
5. **Opportunities for up selling and Cross-selling:** Once a customer is subscribed, it's easier to introduce them to higher-tier plans with more features (upselling) or complementary products/ services (cross-selling), further increasing revenue.

Advantages of the Subscription Model - For Customers:

1. **Convenience and Accessibility:** Subscriptions offer a hassle-free experience. Customers don't have to remember to repurchase a product or service, as it's delivered or renewed automatically. This is particularly valuable for physical products like meal kits or essential goods.
2. **Lower Upfront Cost:** For expensive products or software, a subscription model can make them more affordable by breaking the cost into smaller, manageable payments over time.
3. **Access to Continual Updates and Improvements**: In the case of software or digital content, subscribers often receive automatic updates, new features, or fresh content without any additional cost. This ensures they always have access to the latest version of the product.
4. **Personalization and Discovery:** Many subscription services use customer data to offer personalized recommendations or curated boxes of products, allowing customers to discover new items they might enjoy.

Disadvantages of the Subscription Model - For Businesses:

1. **Customer Acquisition Costs (CAC):** Acquiring a new subscriber often requires a significant upfront investment in marketing and promotions, such as free trials or steep discounts. If the customer churns before the company can recoup this cost, the business can lose money.
2. **High Churn Risk:** While subscriptions can lead to loyalty, they also face the constant risk of churn. Customers can easily cancel if they no longer perceive the value of the service, if they

forget they are subscribed, or if they are enticed by a competitor. Businesses must continuously prove their value to retain subscribers.

3. **Pressure to Deliver Constant Value:** To combat churn, businesses are under continuous pressure to provide new content, features, or improvements. This requires ongoing investment and can be resource-intensive, potentially outweighing the subscription payments if not managed effectively.
4. **Operational and Billing Complexity:** Managing recurring payments, different billing cycles, and various subscription tiers can be complex. Companies need a robust billing and customer management system to handle upgrades, downgrades, cancellations, and failed payments.

Disadvantages of the Subscription Model - For Customers:

1. **Accumulated Costs and "Subscription Fatigue":** While individual monthly fees may seem low, the cost of multiple subscriptions can quickly add up. Customers may find themselves paying for more services than they actually use, leading to "subscription fatigue" and a desire to cancel.
2. **Lack of Ownership:** With many digital subscriptions (e.g., streaming services, software), customers are paying for access rather than ownership. If they cancel their subscription, they lose access to the content or service.
3. **Vendor Lock-in:** Once a customer is integrated into a subscription ecosystem, it can be difficult and inconvenient to switch to a competitor, even if a better or cheaper alternative exists. This is known as "vendor lock-in."
4. **Unwanted Products or Services:** In the case of curated subscription boxes, customers may receive items they don't want or need, leading to waste and dissatisfaction.

3.11. Freemium Model - Advantages and Disadvantages

The freemium model is a business strategy where a company offers a basic version of its product or service for free, while a more comprehensive or advanced version, with additional features, functionality, or a better user experience, is offered for a premium price. The term itself is a portmanteau of "free" and "premium." This model is particularly popular in the software, gaming, and digital services industries because the marginal cost of serving an additional free user is often very low. The goal is to attract a large user base with the free offering and then convert a small percentage of those users into paying customers. The freemium model operates on a few key principles:

1. **Lowering the Barrier to Entry:** By offering a free version, a company removes the initial financial risk for potential users. This encourages widespread adoption and allows the product to gain a foothold in the market quickly.
2. **Delivering Value in the Free Tier:** The free version must be genuinely useful and provide enough value to retain users. If the free product is too limited or frustrating, users will simply abandon it.
3. **Creating a Clear Path to Premium:** The free version is strategically designed to demonstrate the value of the premium features. Limitations in the free tier, such as limited storage, a cap on

usage, ads, or a lack of advanced features, serve as a clear incentive for users to upgrade.

4. **Monetizing a Small Percentage:** The business's revenue relies on a small but highly engaged portion of the user base who are willing to pay for the premium version. The revenue from these paying users must be sufficient to cover the costs of supporting the entire user base, both free and paid.

There are several ways companies implement the freemium model:

1) **Limited Features:** The free version has a basic set of features, while the paid version unlocks all functionalities.
2) **Limited Capacity/Usage:** The free tier restricts usage in some way, such as a data storage limit, a number of projects, or a time limit for video calls. (e.g., Dropbox's free storage limit, Zoom's 40-minute meeting cap).
3) **Advertising:** The free version is supported by ads, while the premium version is ad-free. This is a common strategy for media and streaming services.
4) **Limited Support:** Non-paying users may only have access to a basic level of customer support, while premium users get priority or live support.

Advantages of the Freemium Model

1. **Rapid User Acquisition:** The primary advantage is the ability to attract a massive user base quickly and at a low cost. Since there is no financial barrier to entry, potential customers are more likely to try the product, which can lead to rapid adoption and market penetration.
2. **Increased Brand Awareness:** A large base of free users acts as a powerful marketing tool. Satisfied users can become brand ambassadors, spreading the word through organic channels and social media. This "word-of-mouth" marketing can lead to viral growth and significant brand recognition without high advertising costs.
3. **Customer Data and Insights:** A large user base, even if non-paying, provides a wealth of data on user behavior, preferences, and usage patterns. This information is invaluable for market research, identifying popular features, and guiding future product development.
4. **Upsell Opportunities:** The freemium model is designed to create a direct path for conversion. By providing enough value in the free version to make the product useful, a company can then highlight the benefits of premium features, incentivizing users to upgrade.
5. **Lower Customer Acquisition Cost (CAC):** Since the initial acquisition is based on a free offering, the cost to bring a user into the product's ecosystem is minimal. The marketing and sales effort can then be focused on converting the most engaged free users into paying customers, which is often more efficient than trying to acquire new paying customers from scratch.
6. **Barrier to Competition:** By building a large and loyal user base, a company can create a significant competitive advantage. Once users are accustomed to a product, they are less likely to switch to a competitor, even if a similar service is offered for free.

Disadvantages of the Freemium Model

1. **Low Conversion Rates:** The biggest challenge of the freemium model is the typically

low conversion rate from free to paid users. If the free version is too good, users may never see a reason to upgrade. A low conversion rate can lead to an unsustainable business, as the costs of supporting a large free user base may outweigh the revenue from a small number of paying customers.

2. **High Operational Costs:** Even though free users don't generate direct revenue, they still incur costs. Companies must invest in infrastructure, servers, customer support, and product development to support a large number of non-paying users. If not carefully managed, these costs can quickly outpace revenue and lead to financial difficulties.
3. **Risk of Devaluing the Product:** By offering a product for free, a company runs the risk of devaluing its brand. Some users may perceive the product as "cheap" or not worth paying for, making it harder to justify the premium price point to potential customers.
4. **Strain on Customer Support:** While premium users expect a certain level of support, free users may also demand assistance. This can put a significant burden on the customer support team, diverting resources from the paying customers who are the primary source of revenue.
5. **Difficulty in Balancing Features:** Finding the right balance between the free and premium versions is a constant challenge. The free version must be valuable enough to attract and retain users, but not so valuable that it eliminates the incentive to upgrade. Striking this balance requires careful planning and continuous adjustment based on user data.
6. **Revenue Uncertainty:** Relying on a small percentage of users to convert makes revenue unpredictable. This can make it difficult for businesses to forecast growth, secure funding, or plan for long-term investments.

3.12. Dynamic Model-Advantages and Disadvantages

The term “Dynamic Model” can refer to a few different concepts in business, but most commonly it relates to **dynamic business modeling** and **dynamic pricing**. Both concepts are centered on the idea of a system that is constantly changing and adapting in response to various inputs.

I. Dynamic Business Modeling: This approach involves creating a simulation of a business to understand how its components interact and change over time. It’s a “living” model that mimics real-world behavior, accounting for factors like feedback loops, delays, and a business’s capacity to adapt.

Advantages of Dynamic Business Modeling:

1) **Enhanced Decision-Making:** Unlike static models, a dynamic model can simulate different scenarios and show how various decisions will play out over time. This helps managers make more informed, proactive choices about strategy, resource allocation, and risk management.

2) Deeper Understanding of the Business: By mapping out the interdependencies between different parts of the business, such as sales, marketing, production, and customer behavior, the model provides a holistic view. This helps identify bottlenecks, unexpected consequences of actions, and key drivers of growth.

3) Predictive Capability: Dynamic models can use historical data to forecast future behavior. This is very useful for anticipating market shifts, customer trends, and the impact of external forces like a new competitor or a change in regulations.

4) Improved Communication and Alignment: A visual, dynamic model can serve as a shared language for all stakeholders, from executives to operational teams. It makes complex systems easier to understand and helps ensure everyone is aligned on the business's strategy and how it works.

5) Strategic Adaptability: The model recognizes that businesses evolve. It provides a framework for analyzing how a company's business model can change and adapt to new technologies, market demands, and competitive pressures.

Disadvantages of Dynamic Business Modeling:

1) Complexity and High Cost: Building an accurate and useful dynamic model requires specialized expertise in systems thinking, data analysis, and modeling software. The initial investment in time, money, and skilled personnel can be significant.

2) Dependency on Data Quality: The model's outputs are only as good as the data and assumptions that go into it. Inaccurate, incomplete, or flawed data will lead to misleading results and poor decisions.

3) Oversimplification of Reality: While dynamic models are more sophisticated than static ones, they are still a simplified representation of a complex, real-world business. It's difficult to account for every human and external variable, and a model may not capture the full nuance of a situation.

II. Dynamic Pricing: This is a specific type of dynamic business model that focuses on adjusting prices in real-time based on market conditions, competitor pricing, customer demand, and other factors. It's widely used in industries like airlines, ride-sharing, and e-commerce.

Advantages of Dynamic Pricing :

1) Revenue Optimization: The primary goal is to find the "sweet spot"—the highest price a customer is willing to pay at a given moment. This allows businesses to maximize revenue by increasing prices during periods of high demand and lowering them to clear inventory or attract customers during slow periods.

2) Increased Flexibility and Competitiveness: Dynamic pricing allows a business to respond instantly to market changes, such as a competitor's price drop or a sudden spike in demand. This agility can be a significant competitive advantage.

3) Inventory and Supply Management: By using pricing to influence demand, businesses can manage their inventory more effectively, reducing waste and the costs associated with overstocking or under-stocking.

4) Data-Driven Insights: The data collected for dynamic pricing provides a deep understanding of customer behavior, price sensitivity, and market trends, which can be used to improve

overall business strategy.

Disadvantages of Dynamic Pricing:

1) Customer Dissatisfaction and Lack of Trust: Continually fluctuating prices can confuse or frustrate customers. If they feel like they are being unfairly charged a higher price, it can damage brand loyalty and lead to a loss of customers.

2) Potential for Price Wars: If competitors also use dynamic pricing, it can lead to a "race to the bottom" where companies constantly undercut each other, eroding profit margins for everyone in the market.

3) Ethical and Legal Concerns: Dynamic pricing can be seen as discriminatory if prices are adjusted based on a customer's location, browsing history, or willingness to pay, raising ethical questions and potential for regulatory scrutiny.

4) Implementation Complexity: Setting up and managing a dynamic pricing system is a complex task. It requires sophisticated algorithms, real-time data collection, and continuous monitoring to ensure the system is working as intended and not making costly errors.

Short Type Questions :

1. Freemium Model
2. Digital and Technological Economies
3. Subscription Model
4. Dynamic Model
5. Cost Concepts

Essay Type Questions :

1. Explain Relationship - AR and MR in Perfect Competition Market
2. Expalin Relationship - AR and MR in Imperfect Competition Market
3. Describe Subscription Model-Advantages and Disadvantages
4. Explain Freemium Model-Advantages and Disadvantages
5. Describe Dynamic Model-Advantages and Disadvantages

4.1. Features of Monopoly

The word monopoly has been derived from the combination of two words i.e., 'Mono' and 'Poly'. Mono refers to a single and poly to control. In this way, monopoly refers to a market situation in which there is only one seller of a commodity. There are no close substitutes for the commodity it produces and there are barriers to entry. The single producer may be in the form of individual owner or a single partnership or a joint stock company. In other words, under monopoly there is no difference between firm and industry.

Monopolist has full control over the supply of commodity. Having control over the supply of the commodity he possesses the market power to set the price. Thus, as a single seller, monopolist may be a king without a crown. If there is to be monopoly, the cross elasticity of demand between the product of the monopolist and the product of any other seller must be very small. Pure or absolute monopoly exists when a single firm is the sole producer for a product for which there are no close substitutes. We may state the features of monopoly as:

1. **One Seller and Large Number of Buyers:** The monopolist's firm is the only firm; it is an industry. But the number of buyers is assumed to be large.

2. **No Close Substitutes:** There shall not be any close substitutes for the product sold by the monopolist. The cross elasticity of demand between the product of the monopolist and others must be negligible or zero.

3. **Difficulty of Entry of New Firms:** There are either natural or artificial restrictions on the entry of firms into the industry, even when the firm is making abnormal profits.

4. **Monopoly is also an Industry:** Under monopoly there is only one firm which constitutes the industry. Difference between firm and industry comes to an end.

5. **Price Maker:** Under monopoly, monopolist has full control over the supply of the commodity. But due to large number of buyers, demand of any one buyer constitutes an infinitely small part of the total demand. Therefore, buyers have to pay the price fixed by the monopolist.

6. Nature of Demand and Revenue under Monopoly : Under monopoly, it becomes essential to understand the nature of demand curve facing a monopolist. In a monopoly situation, there is no difference between firm and industry. Therefore, under monopoly, firm's demand curve constitutes the industry's demand curve. Since the demand curve of the consumer slopes downward from left to right, the monopolist faces a downward sloping demand curve. It means, if the monopolist

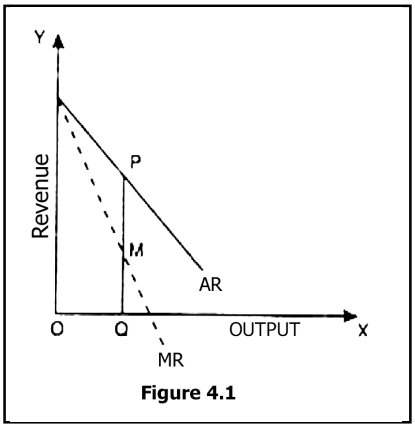

Figure 4.1

reduces the price of the product, demand of that product will increase and vice-versa.

In Fig. 4.1 average revenue curve of the monopolist slopes downward from left to right. Marginal revenue (MR) also falls and slopes downward from left to right. MR curve is below AR curve showing that at OQ output, average revenue (= Price) is PQ where as marginal revenue is MQ. That way AR > MR or PQ > MQ.

7. Costs under Monopoly: Under monopoly, shape of cost curves is similar to the one under perfect competition. Total fixed costs curve is parallel to OX-axis whereas average fixed cost is rectangular hyperbola.

Moreover, average variable cost, marginal cost and average cost curves are of U-shape. Under monopoly, marginal cost curve as in the perfect competition. Price is higher than marginal cost.

4.2. Price determination and equilibrium of the firm under Monopoly

Under monopoly, for the equilibrium and price determination there are two different conditions which are: 1. Marginal revenue must be equal to marginal cost. 2. MC must cut MR from below.

1. Short Run Equilibrium under Monopoly: Short period refers to that period in which the monopolist has to work with a given existing plant. In other words, the monopolist cannot change the fixed factors like, plant, machinery etc. in the short period. Monopolist can increase his output by changing the variable factors. In this period, the monopolist can enjoy super-normal profits, normal profits and sustain losses.

i) Super Normal Profits : If the price determined by the monopolist in more than AC, he will get super normal profits. The monopolist will produce up to the level where MC =

MR. This limit will indicate equilibrium output.

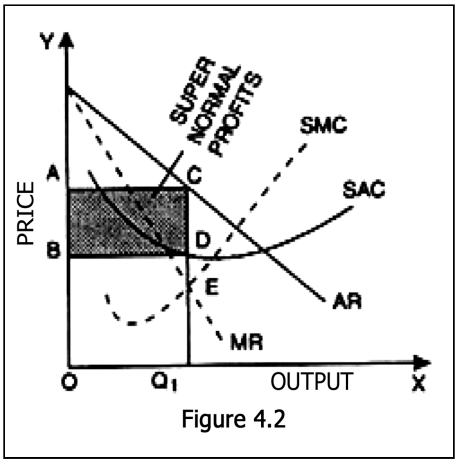

Figure 4.2

In Figure 4.2 output is measured on X-axis and price on Y-axis. SAC and SMC are the short run average cost and marginal cost curves while AR or MR are the average revenue or marginal revenue curves respectively. The monopolist is in equilibrium at point E because at point E both the conditions of equilibrium are fulfilled i.e., MR = MC and MC intersects the MR curve from below. At this level of equilibrium the monopolist will produce OQ1 level of output and sells it at CQ1 price which is more than average cost DQ1 by CD per unit. Therefore, in this case total profits of the monopolist will be equal to shaded area ABDC.

ii) Normal Profits : A monopolist in the short run would enjoy normal profits when average revenue is just equal to average cost. It is important to know average cost of production is inclusive of normal profits. This situation can be illustrated with the help of fig 4.3. In the figure the firm is in equilibrium at point E. Here marginal cost is equal to marginal revenue. The firm is producing OM level of output. At OM level of output average cost curve touches the average revenue curve at point R. Therefore, at point 'R' price MR is equal to average cost of the total product. In this way, monopoly firm enjoys the normal profits.

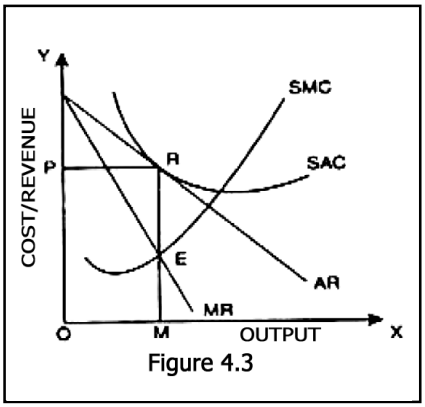

Figure 4.3

iii) Minimum Losses : In the short run, the monopolist may have to incur losses. This situation occurs if in the short run price falls below the variable cost. In other words, if price falls due to depression and fall in demand, the monopolist will continue to produce as long as price covers the average variable cost. Once the price falls Below the average variable cost, monopolist will stop production. Thus, a monopolist in the short run equilibrium has to bear the minimum loss equal to fixed costs. Therefore, equilibrium price will be equal to average variable cost. This situation can also be explained with the help of Fig. 4.4.

In Fig. 4.4 monopolist is in equilibrium at point E. At point E marginal cost is equal to marginal revenue and he produces OM level of output. At OM level of output, equilibrium price fixed by the monopolist is OP1. At OP1 price, SAVC touches the AR curve at point A. It signifies that the firm will cover only average variable cost from the prevailing price. At OP1 price, firm will bear loss of fixed cost i.e., AN per unit. The firm will bear the total loss equal to the shaded area PNAP1. Now if the price falls below OP1, the monopolist will stop production. It is so because if he continues production, he he has to bear the loss of variable costs along with fixed costs.

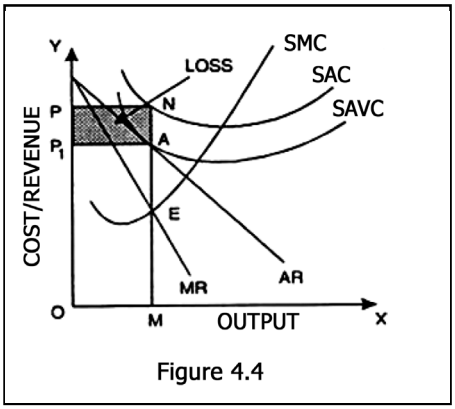

Figure 4.4

2. Long Run Equilibrium under Monopoly: Long-run is the period in which output can be changed by changing the factors of production. In other words, all variable factors can be changed and monopolist would choose that plant size which is most appropriate for specific level of demand. Here, equilibrium would be attained at that level of output where the long-run marginal cost cuts marginal revenue curve from below. This can be shown with the help of Fig. 4.5. In Figure monopolist is in equilibrium at OM level of output. At OM level of output marginal revenue is equal to long run marginal cost and the monopolist fixes OP price.

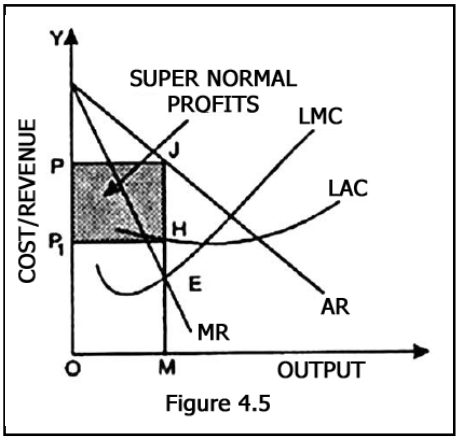

Figure 4.5

Price OP (JM) being more than LAC i.e., HM which fetch the monopolist super normal profits. Accordingly, the monopolist earns JM - HM = JH super normal profit per unit. His total super normal profits will be equal to shaded area $PJHP_1$

4.3 . Price Discrimination under Monopoly

In monopoly, there is a single seller of a product called monopolist. The monopolist has control over pricing, demand, and supply decisions, thus, sets prices in a way, so that maximum profit can be earned. The monopolist often charges different prices from different consumers for the same product. This practice of charging different prices for identical product is called price discrimination. According to Robinson, "Price discrimination is charging different prices for the same product or same price for the differentiated product."

Types of Price Discrimination : Price discrimination is a common pricing strategy' used by a monopolist having discretionary pricing power. This strategy is practiced by the monopolist to gain market advantage or to capture market position.

1. **Personal :** Refers to price discrimination when different prices are charged from different individuals. The different prices are charged according to the level of income of consumers as well as their willingness to purchase a product. For example, a doctor charges different fees from poor and rich patients.
2. **Geographical :** Refers to price discrimination when the monopolist charges different prices at different places for the same product. This type of discrimination is also called dumping.
3. **On the basis of use :** Occurs when different prices are charged according to the use of a product. For instance, an electricity supply board charges lower rates for domestic consumption of electricity and higher rates for commercial consumption.

4.4. Degrees of Price Discrimination

A.C. Pigou in his publication "Economics of Welfare" has classified the price discrimination into 3 types on the basis of Degree of capturing or exploiting consumer surplus. Price discrimination has become widespread in almost every market. In economic jargon, price discrimination is also called monopoly price discrimination or yield management. There are three degrees of price discrimination explained as follows:

1. **First-degree Price Discrimination :** Refers to a price discrimination in which a monopolist charges the maximum price that each buyer is willing to pay. This is also known as perfect price discrimination as it involves maximum exploitation of consumers. In this, consumers fail to enjoy any consumer surplus. First degree is practiced by lawyers and doctors.

2. **Second-degree Price Discrimination :** Refers to a price discrimination in which buyers are divided into different groups and different prices are charged from these groups depending upon what they are willing to pay. Railways and airlines practice this type of price discrimination.

3. **Third-degree Price Discrimination :** Refers to a price discrimination in which the monopolist divides the entire market into two submarkets and different prices are charged in each submarket. Therefore, third-degree price discrimination is also termed as market segmentation.

Equilibrim of the firm under discriminating monopoly

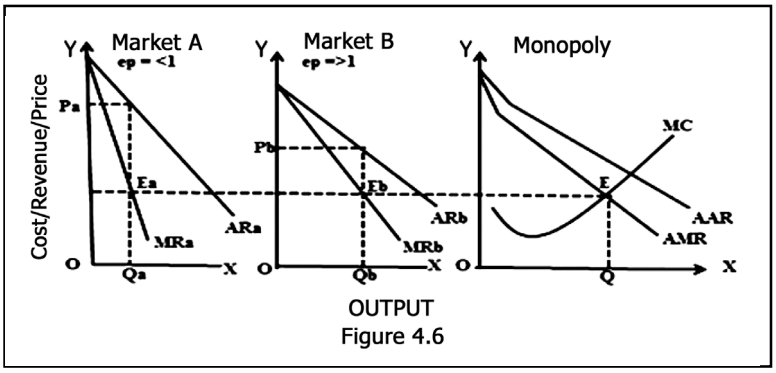

Figure 4.6

Assume that a monopolist has divided market into two submarkets, A and B. He found that the elasticity of demand is greater in market B than in market A. The monopolist would earn maximum profits where MR=MC and MC curve cuts MR curve from below, which is shown in Figure 4.6. In Figure 4.6, in case of total market, output OQa has to be distributed in such a way that AMR equals MC at E.

Thus, a monopolist will sell output OQa in market A and OQb in market B as at these levels of output equals OQ that is an equilibrium output. The price charged in both the markets will be equal to AAR or demand curve.

Thus, price in market A is OPa and price in market B is OPb. It should be noted that the price charged in market A is greater than the price charged in market B. This is because the elasticity of demand is greater in market B than A. Since price in market A is higher, the output sold is low that is OQa than OQb in market B.

Thus, there must be two conditions for a discriminating monopolist to attain equilibrium given as follows:

1. Marginal Cost of Total Output = Combined Marginal Revenue.

2. Marginal Revenue in Market A = Marginal Revenue in Market B=Marginal Cost.

4.5. Monopoly Power in Tech Firms

Monopoly power in tech firms refers to the ability of a few large companies, often called "Big Tech," to dominate a market, control pricing, and stifle competition. This dominance is often achieved through a "winner-takes-all" dynamic, where network effects, massive data collection, and significant capital allow a company to create barriers to entry for competitors. Tech companies gain and maintain monopoly power through several key strategies:

1. **Network Effects**: For some platforms, the more users there are the more valuable the service becomes. This creates a powerful self-reinforcing cycle. For example, a social media platform like Face book becomes more useful as more people join, making it difficult for new competitors to attract a user base.

2. **Data and Intellectual Property**: Tech firms collect vast amounts of user data, which gives them a significant competitive advantage in developing new products, improving services, and targeting advertising. This data, along with patents and copyrights, creates a moat around their business that is difficult for others to cross.

3. **Economies of Scale**: The initial cost of developing software or building a digital platform is often very high, but the cost of distributing it to millions of users is near zero. This allows dominant firms to produce and deliver their products at a much lower average cost than any potential competitor, making it nearly impossible for new entrants to compete on price.

4. **Mergers and Acquisitions**: Large tech companies frequently acquire smaller, innovative startups that pose a potential competitive threat. This strategy eliminates rivals before they can grow large enough to challenge the incumbent's market position, consolidating the market and reinforcing the dominant firm's power. For instance, Meta acquired Instagram and WhatsApp, and Google has acquired over 200 companies, including YouTube.

4.6. Antitrust laws

Antitrust laws, also known as competition laws, are a body of government regulations designed to promote and maintain fair competition in the marketplace. Their primary purpose is to prevent monopolies, cartels, and other anti-competitive practices that can harm consumers, stifle innovation, and lead to higher prices.

The foundation of U.S. antitrust law is a trio of federal statutes passed in the late 19th and early 20th centuries:

1. **The Sherman Antitrust Act (1890):** This is the cornerstone of U.S. antitrust law. It has two main sections:

> **Section 1** prohibits contracts, combinations, or conspiracies that restrain trade. This targets agreements between competitors, such as price-fixing, bid-rigging, and market allocation.
>
> **Section 2** makes it illegal to monopolize, attempt to monopolize, or conspire to monopolize any part of trade or commerce. It's important to note that simply being a monopoly is not illegal; the law targets the abusive and anti-competitive actions taken to gain or maintain that monopoly.

2. **The Clayton Antitrust Act (1914):** This law addresses specific practices that the Sherman Act didn't explicitly cover. It prohibits actions that "substantially lessen competition or tend to create a monopoly." Key provisions include:

1) Banning certain types of mergers and acquisitions that would reduce competition.
2) Prohibiting price discrimination (selling the same product at different prices to different buyers without a legitimate justification).
3. **The Federal Trade Commission Act (1914):** This law created the Federal Trade Commission (FTC), an agency with broad authority to investigate and prevent "unfair methods of competition" and "unfair or deceptive acts or practices." The FTC and the U.S. Department of Justice (DOJ) are the two primary federal agencies responsible for enforcing antitrust laws.

Antitrust laws are used to prosecute a wide range of anti-competitive behaviors :

1) **Price-fixing:** Competitors agreeing to set prices for their products or services at a certain level, rather than letting the market determine them.
2) **Bid-rigging:** Competitors colluding to determine who will win a bid for a contract, often by having some competitors submit artificially high bids.
3) **Market allocation:** Competitors dividing a market among themselves, agreeing not to compete in certain geographic areas or for certain customers.
4) **Monopolization:** A dominant firm using its market power to exclude competitors, such as through predatory pricing (setting prices so low as to drive rivals out of business) or tying arrangements (requiring a customer to buy one product to get another).

5) **Anti-competitive mergers:** A merger between two companies that would significantly reduce competition in a market. The government can block or impose conditions on such mergers to protect consumers.

4.7. Digital Market Monopolies

Digital market monopolies refer to a situation where a single company or a few companies gain significant control over a digital market or a digital ecosystem. These companies are often referred to as "Big Tech" and include giants like Google, Amazon, Meta (Facebook), Apple, and Microsoft.

Characteristics of Digital Monopolies :

1. **Network Effects:** The value of a service increases as more people use it. For example, a social network is more useful to you if your friends are on it, which makes it difficult for new competitors to attract users.
2. **Data Control:** These companies collect and control vast amounts of user data, which allows them to improve their products, personalize services, and gain a significant competitive advantage in targeted advertising.
3. **Ecosystem Lock-in:** Dominant firms create an interconnected ecosystem of products and services (e.g., an operating system, app store, and cloud storage) that makes it inconvenient and costly for users to switch to a competitor.
4. **Economies of Scale:** Operating at a large, often global, scale allows these companies to lower their per-unit costs and offer services at a price that smaller competitors cannot match.

Examples and Practices: While the term "monopoly" strictly means a single seller, in the digital context, it often refers to a dominant position that allows a company to act without significant competitive pressure. Examples of this include:

1) **Google Search:** With a very high market share in web search, Google is often cited as a de facto monopoly.

2) **Meta (Facebook):** Its control over social networking through platforms like Facebook, Instagram, and WhatsApp gives it a dominant position in the social media and advertising markets.

3) **Amazon:** As the world's largest e-commerce site, Amazon holds a monopsony (a single buyer) position in the e-book market and exerts significant influence over third-party sellers on its platform.

Digital monopolies are often accused of engaging in anti-competitive practices to maintain their dominance, such as:

1) **Self-Preferencing:** Favoring their own products or services on their platforms (e.g., a search engine promoting its own comparison shopping service).

2) **Bundling and Tying:** Combining or bundling services to force users to buy related products.

3) **Predatory Acquisitions:** Acquiring nascent competitors to eliminate a potential future threat. A prime example often cited is Meta's acquisition of Instagram and WhatsApp.

4) **Anti-Steering:** Hindering business users from directing consumers to lower-priced alternatives outside of the dominant platform.

4.8. Features of Monopolistic Competition

The two important subdivisions of imperfect competition are monopolistic competition and oligopoly. Most of the economic situations **"are composites of both perfect competition and monopoly".** Chamberlin's monopolistic competition is an amalgam or an admixture of perfect competition and monopoly.

1. **Large Number of Sellers :** Like perfect competition, there are a large number of sellers and buyers. But the 'number' is not too large like perfect competition. As a result, each firm has an insignificant share in the market so that action of one seller does not affect rival sellers to any great extent.

2. **Differentiated Products :** Sellers sell differentiated products, but they are close but not perfect substitutes. It is the degree of differentiation that creates both monopoly and competitive elements. Every product is unique to the buyers. So every seller enjoys some degree of monopoly of his own product over other sellers.

3. **Elastic Demand Curve :** Since product of each seller is slightly different from his rivals he enjoys some degree of monopoly power and, hence, can raise the price of his product without losing most customers. But as other rival firms produce closely related goods, every firm faces competition and its influence over the price of the product is rather limited. Thus, each firm has a downward sloping demand curve implying that it behaves as a price-maker.

4. **Non-Price Competition :** Besides price competition, Chamberlin suggested cases of non-price competition that arise due to product variation and selling activities. Seller always tries to establish the fact that his product is superior to others by improving the quality of his product. And in doing so, he incurs selling costs or makes advertisement to attract more customers in his fold.

5. **Free Entry-Exit :** Like perfect competition, there is complete freedom of entry and exit.

6. **Product Group :** Chamberlin used the term 'group' rather than industry. An industry is a set of firms that produces homogeneous goods. But under monopolistic competition, goods are heterogeneous or slightly differentiated. Thus, the term 'industry' cannot be applied here. That is why Chamberlin used 'product group' which is defined as a collection of firms producing almost similar goods, but not identical goods.

4.9. Price Determination and Equilibrium of the Firm under Monopolistic Competition

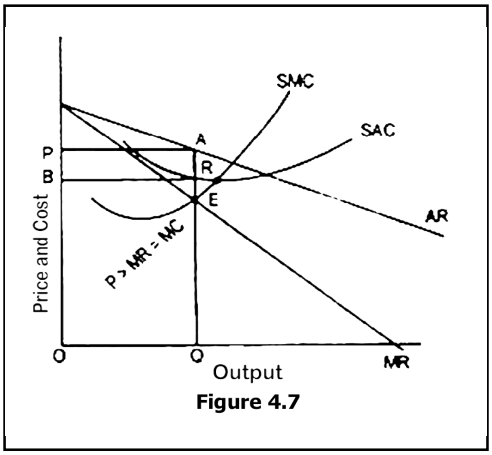

Figure 4.7

Short Run Equilibrium: Equilibrium of a firm under monopolistic competition is often understood in terms of short period and long period. In the short run, Chamberlin's model of monopolistic competition comes closer to monopoly.

That is to say, there is virtually no difference between monopolistic competition and monopoly in the short run. Thus, Chamberlin's firm may earn supernormal profit, normal profit, or incur loss in the short run, since entry and exit are not allowed during this time period.

In Fig. 4.7, the short run marginal cost curve, SMC, is equal to MR at point E. Thus E is the equilibrium point. Corresponding to this equilibrium point, the firm produces OQ output and sells it at a price OP. Thus, the firm earns supernormal profit to the extent of PARB since total revenue (OPAQ) exceeds total cost of production (OBRQ).

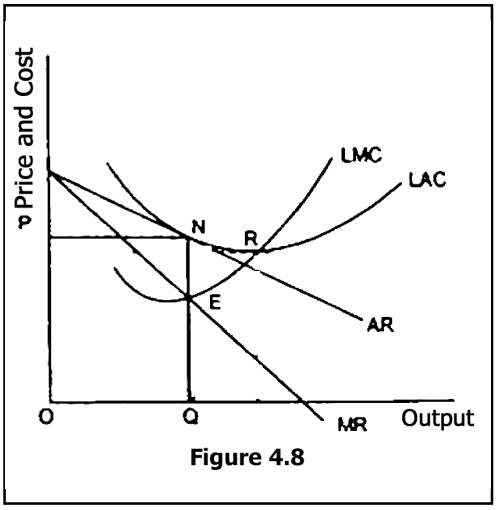

Figure 4.8

A firm, in the short run, may earn only normal profit if MC = MR < AR = AC occurs. A loss may result in the short run if MC = MR < AR < AC happens.

Long Run Equilibrium: In the long run, monopolistic competition comes closer to perfect competition because the freedom of entry and exit allows firms to enjoy only normal profit. Whenever some firms earn supernormal profit in the long run some other firms may be attracted to join this product group, thereby shifting the demand curve or AR curve downward and to the left. Thus, entry of new firms would cause decline in market share by reducing the demand for its product.

Long run equilibrium is achieved at point E where LMC equals MR (Fig. 4.8). The equilibrium output thus determined is OQ. At this output, AR equals AC. The firm gets normal profit by selling OQ output at the price OP. Note that a monopolistically competitive firm always operates somewhere to the left of the minimum point (R) of its AC curve.

4.10. Brand Loyalty Monopolistic Competition

In **monopolistic competition**, brand loyalty is a key factor that allows firms to differentiate their products and gain some control over pricing. Unlike in perfect competition where products are identical, monopolistically competitive firms sell products that are **similar but not perfect substitutes**. Brand loyalty is a crucial element of this "product differentiation" because it makes a firm's demand curve less elastic. The Brand Loyalty Works as under:

1. **Product Differentiation**: Firms in a monopolistically competitive market use branding, advertising, and unique features to make their products stand out. This creates a perceived difference in the minds of consumers. For example, while many brands sell running shoes, Nike differentiates itself through its brand image, endorsements, and marketing.
2. **Reduced Price Sensitivity**: When consumers are loyal to a brand, they become less sensitive to price changes. They might be willing to pay a slightly higher price for their preferred brand rather than switching to a competitor's cheaper alternative. This gives the firm some **market power** and the ability to act as a **price maker**, even though to a limited extent.
3. **Barriers to Entry**: Strong brand loyalty can act as a minor barrier to entry for new firms. A new entrant must not only offer a comparable product but also spend considerable resources on advertising and marketing to convince consumers to switch from their established, loyal brands.

In monopolistic competition, a firm's demand curve is **downward-sloping**. This is a direct result of product differentiation and brand loyalty. If a firm raises its price, it won't lose all of its customers because some will remain loyal to the brand. Conversely, if it lowers its price, it will attract some new customers from competing brands. The degree of brand loyalty determines the **elasticity** of the demand curve:

1. High brand loyalty leads to a more inelastic demand curve (steeper slope), meaning a price change has a smaller effect on the quantity demanded.
2. Low brand loyalty leads to a more elastic demand curve (flatter slope), meaning a price change has a larger effect on the quantity demanded.

4.11. Consumer Psychology in Monopolistic Competition

In monopolistic competition, consumer psychology is crucial because firms don't just compete on price; they compete on **product differentiation**. Consumer psychology is the key that unlocks the ability for a firm to create and exploit these perceived differences. Firms influence psychological principles to influence consumer behavior and build brand loyalty.

1. **Product Perception:** Consumers don't view products as perfect substitutes. Through branding, packaging, and marketing, firms create a perception that their product is unique and superior.

2. **Brand Loyalty:** This is the ultimate goal of non-price competition. Firms use advertising and brand image to foster a strong emotional connection with consumers. A loyal customer base is less price-sensitive and more likely to make repeat purchases. This loyalty is often based on trust, a positive past experience, and a sense of shared values with the brand. Consumers may even act as brand ambassadors, promoting the product through word-of-mouth.

3. **The "Illusion of Choice":** While a monopolistically competitive market offers many products, firms often segment the market and offer slightly different versions of the same product to different consumer groups. This creates an **illusion of extensive choice**, which can overwhelm consumers but also make them feel that a brand is specifically tailored to their needs. For example, one company might offer dozens of different flavors and varieties of a single food product.

4. Psychological Pricing: Firms employ various pricing strategies that tap into consumer psychology. These include:

1) **Charm Pricing:** Setting prices that end in .99 or .95 to create the perception of a lower price (e.g., $9.99 instead of $10.00). Consumers are more likely to focus on the left-most digit, making the price seem more appealing.
2) **Prestige Pricing:** Setting a high price to signal quality, exclusivity, and status. Consumers may associate a higher price with a superior product, even if the difference in cost is minimal. Luxury goods and certain tech products often use this strategy.
3) **Creating Awareness:** In a crowded market, advertising helps a brand stand out from the noise and get noticed.
4) **Influencing Perceptions:** Ads don't just inform; they persuade. They create a brand image and tell a story that resonates with consumers on an emotional level.

• **Building Brand Identity:** A brand's identity – its personality, values, and what it represents – is built through consistent messaging and advertising. Consumers who identify with that brand are more likely to become loyal customers.

4.12. Social Media in Monopolistic Competition

Social media platforms fit well into the economic model of **monopolistic competition**, a market structure where many firms offer products that are similar but not perfect substitutes. They are not true monopolies in the strict sense because users can and do switch between platforms.

Characteristics of the Social Media Market

1. **Many firms**: There are numerous social media platforms, including Facebook, Instagram, TikTok, Twitter (X), LinkedIn, and Snapchat, all competes for users' attention.
2. **Differentiated products**: Each platform offers a unique user experience. Instagram and TikTok focus on visual content and short videos, while LinkedIn is for professional networking. This differentiation is the key feature that distinguishes monopolistic competition from perfect competition, where products are identical.
3. **Some control over price**: While most platforms are free for users, they earn revenue by selling advertising space. The product differentiation and brand loyalty they build give them some control over the prices they charge advertisers. For example, a firm might pay more to advertise on a specific platform because it offers unique targeting capabilities or access to a particular demographic.
4. **Low barriers to entry**: While developing a new platform can be costly, the theoretical barriers to entry are low compared to a natural monopoly like a utility company. New platforms can emerge and gain traction quickly, as seen with the rapid rise of TikTok.

   Social media has a deep impact on firms operating in monopolistically competitive markets. It serves as a powerful tool for product differentiation and brand building.

   1) **Marketing and Advertising**: Social media allows businesses to reach specific consumer groups with targeted advertising. This is a core strategy in monopolistic competition, where firms must constantly persuade consumers that their product is superior or different from their competitors'.
   2) **Customer Engagement**: Social media provides a direct channel for firms to interact with their customers, gather feedback, and build a community around their brand. This helps to foster brand loyalty and create a "moat" around the business, making it less likely for customers to switch to a competitor.
   3) **Shaping Consumer Preferences**: By using influencers and viral trends, firms can use social media to shape consumer tastes and preferences. This allows them to influence the demand for their product, which is a key characteristic of a firm in a monopolistically competitive market.

In summary, while the market for social media as a whole is a classic example of monopolistic competition, the power of a few key players to acquire competitors and leverage network effects raises questions about whether they are shifting towards a more monopolistic or oligopolistic structure.

4.13. Collusion in Digital Market Places

Collusion in digital marketplaces, or **algorithmic collusion**, is a significant and growing concern for regulators and economists. While traditional collusion involves explicit communication between rivals to fix prices or divide markets, digital marketplaces present new, often subtle, ways for firms to achieve the same anti-competitive outcomes. The primary driver of this new form of collusion is the widespread use of **pricing algorithms**.

Pricing algorithms are automated systems that set prices for products and services based on a variety of data, including competitor prices, demand, and inventory levels. They can lead to two main types of collusion:

1. **Explicit Collusion:** In this scenario, algorithms are used as a tool to facilitate an existing agreement between firms. For example, competing sellers on an e-commerce platform might agree to use the same third-party repricing software. The software, acting as a "hub," then implements and maintains the collusive pricing, ensuring no party undercuts the others. This makes it easier to sustain an illegal agreement without direct, risky communication.

2. **Implicit Collusion:** This is the more complex and debated form. Here, there is no explicit agreement between firms. Instead, a firm's pricing algorithm is programmed to react to its competitors' prices in real-time. When multiple firms in a market use similar responsive algorithms, they can "learn" to coordinate their prices to a higher, supra-competitive level. This can happen without any human intervention or intent to collude. This is a form of **conscious parallelism** on a massive, automated scale.

The rise of algorithmic collusion presents major challenges for antitrust authorities:

1) **Difficulty in Detection:** Unlike a paper trail from a secret meeting, there's often no direct evidence of communication or agreement in algorithmic collusion. The behavior may appear to be a normal, unilateral response to market conditions, making it difficult to prove anti-competitive intent.

2) **Defining Intent:** A key element of traditional antitrust law is proving a collusive "agreement." When a collusive outcome arises from autonomous, self-learning algorithms, it's unclear who is legally responsible. Is it the programmer, the firm that deployed the algorithm, or the algorithm itself? This legal ambiguity makes enforcement difficult.

3) **Speed and Scale:** Algorithms can change prices thousands of times a day, making it impossible for regulators to monitor and respond in real-time. The sheer volume and speed of algorithmic pricing also make it challenging to analyze for collusive patterns.

4.14. Platform Competition in Duopoly Market

Platform competition in a duopoly market is a dynamic and complex form of competition between two dominant firms that operate as **platforms**. Unlike traditional firms that sell a product or service, platforms facilitate interactions between two or more distinct groups of users, such as buyers and sellers, creators and consumers, or advertisers and users. The competition between these platforms is heavily influenced by **network effects**, which are the primary driver of market outcomes.

The Role of Network Effects: Network effects are a critical concept in platform competition. They refer to the phenomenon where a platform's value to a user increases as more users join the platform. There are two types of network effects at play:

1. Direct Network Effects: The value of a platform to a user on one side of the market increases as more users on the **same side** of the market join. For example, a social media user benefits from having more friends on the same platform.

2. Indirect (or Cross-Side) Network Effects: The value of a platform to a user on one side of the market increases as more users on the **other side** of the market join. For example, a buyer's experience on an e-commerce site improves as more sellers join, and a seller's experience improves as more buyers join.

In a duopoly, these network effects create a powerful feedback loop. A platform that successfully attracts users on one side of the market becomes more attractive to users on the other side, which in turn makes it more attractive to the first group, and so on. This can lead to a "**winner-take-all**" or "**winner-take-most**" dynamic, even with only two firms.

Competitive Strategies in a Duopoly Platform Market: Because of network effects, platform duopolists don't just compete on price. Their strategies are multifaceted and often involve a mix of pricing, innovation, and exclusive deals.

1. **Pricing Structure**: Platforms often employ a **multi-sided pricing strategy**, where they may subsidize one side of the market to attract users, knowing they will make up the profits from the other side. For instance, a food delivery platform may offer free delivery to customers while charging a high commission to restaurants. In a duopoly, this can lead to a price war on one side of the market as each platform tries to attract a critical mass of users.
2. **Product Differentiation and Innovation**: Platforms compete by offering unique features and services to differentiate themselves. This could be in the form of a better user interface, exclusive content, or superior algorithms.
3. **Exclusive Deals and Tying**: Platforms may try to lock in users by entering into exclusive agreements with key content creators or service providers. This strategy is aimed at raising barriers to entry and making it harder for users to switch platforms.
4. **Multi-homing and Switching Costs**: Multi-homing, where users engage with multiple

platforms at the same time (e.g., using both Uber and Ola), can weaken network effects and intensify competition. Platforms therefore try to increase **switching costs** to make it difficult for users to leave. This could involve making a user's data difficult to transfer or building a brand community that fosters loyalty.

Platform Duopolies

Several markets are dominated by two major platforms that exhibit duopoly-like competition.

1) **Ride-Hailing**: Uber and Ola in India.

2) Food Delivery: Zomato and Swiggy in India.

3) Operating Systems: Android and iOS globally.

4) Online Advertising: Google and Meta (Facebook).

In these markets, the firms are in constant strategic interaction, carefully monitoring each other's moves and adapting their own strategies in response. The outcome for consumers can be mixed; competition can lead to lower prices and innovation, but the strong network effects can also lead to a concentration of power that may eventually harm consumer welfare.

4.15. Digital Market Duopolies

A digital market duopoly is a market structure in which two companies dominate the market for a particular digital product or service. This is the most basic form of an oligopoly, which is a market controlled by a small number of firms. Digital duopolies are common because of factors like network effects, where a service becomes more valuable as more people use it.

Digital Duopolies :

1) **Operating Systems:** Google's Android and Apple's iOS control nearly the entire global Smartphone OS market.
2) **Digital Advertising:** Google and Meta (formerly Facebook) have long dominated the digital advertising space, often referred to as the "digital duopoly."
3) **Ride-Hailing:** In many countries, two companies, such as Uber and Ola in India, dominate the ride-hailing market.

Characteristics and Strategies of Digital duopolies :

1. **Interdependence:** The actions of one firm directly impact the other. For instance, if one platform lowers its advertising rates, the other might be forced to follow suit to avoid losing market share
2. **High Barriers to Entry:** It's incredibly difficult for a new competitor to enter and challenge the two dominant firms due to factors like network effects, brand loyalty, and the vast resources and data they possess.
3. **Acquisitions:** A common strategy for digital duopolists is to buy smaller, innovative rivals that could one day pose a competitive threat. Meta's acquisition of Instagram and WhatsApp is a classic example of this.

Short Type Questions :

1. Digital market duopolies
2. Antitrust laws
3. Monopoly
4. monopolistic competition
5. Brand loyalty
6. Digital market monopolies
7. Monopoly power in Tech firms
8. Degrees of Price Discrimination
9. Collusion in digital market places
10. Social media in Monopolistic competition

Essay Type Questions :

1. Describe Price determination and equilibrium of the firm under Monopoly.
2. Explain Price determination and equilibrium of the firm under Monopolistic competition
3. Explain Price Discrimination under Monopoly.
4. Bring out Consumer psychology in Monopolistic competition.
5. Explain Platform competition in duopoly market.

ANALYSIS OF BUSINESS FIRM, AND PRICING STRATEGIES

5.1. Objectives of Business Firm

5.2. Benefits of ESG consideration in Business Strategy

5.3. Steps included integrating ESG in Business Strategy

5.4. Challenges in ESG integration

5.5. Meaning, Definitions, Formulas and of accounting profit & Economic Profit

5.5.1. Differences between accounting profit and Economic Profit

5.6. Break Even Point

5.7. Role of AI in Profit Optimisation

5.8. Working of AI based pricing models

5.9. Types of AI based pricing models

5.10. Advantages and Disadvantages of AI based pricing models

5.1. Objectives of Business Firm

The objectives of a business firm are the goals and targets that guide its decision-making, strategies, and overall performance. While different economic theories and real-world scenarios present a variety of objectives, they can generally be categorized into a few key areas.

I. Profit Maximization: This is often considered the traditional and primary objective of a business firm in classical economics. The goal is to maximize the difference between total revenue and total cost. Profit maximization is crucial for:

1) **Survival and Growth:** Profits are the lifeblood of a business. They provide the necessary funds for day-to-day operations, reinvestment in the business, paying off debts, and financing future growth and expansion.

2) **Attracting Investors:** High profitability and a track record of strong returns attract investors, which provide the capital needed for innovation and expansion.

3) **Efficient Resource Allocation:** The pursuit of profit encourages firms to use their resources, labor, capital, and raw materials, in the most efficient way possible to reduce costs and increase revenue.

II. Sales/Revenue Maximization: This objective focuses on maximizing total sales or revenue, often at the expense of short-term profit. This strategy is often pursued for several reasons:

1) Market Share: A larger market share can lead to greater market power, making the firm a dominant player in its industry. This can give it a competitive advantage and the ability to influence prices in the long run.

2) Managerial Goals: Managers and executives may be compensated based on sales volume or the size of the company, which can incentivize them to prioritize revenue growth over profit.

3) Economies of Scale: By increasing sales and production, a firm can benefit from economies of scale, which can lead to lower costs per unit in the long run.

III. Growth Maximization: This objective is centered on increasing the size and scale of the firm. Growth can be measured in terms of sales, assets, or market share. A focus on growth can involve:

1) **Mergers and Acquisitions:** Acquiring other companies is a common way to expand a firm's size, reach, and product offerings.

2) **New Market Entry:** Entering new geographical markets or launching new product lines is another way to achieve growth.

3) **Prestige and Power:** For managers, working for a larger, growing company can lead to greater prestige, higher salaries, and more opportunities for career advancement.

IV. Shareholder Wealth Maximization: This objective, often seen in modern corporations, focuses on maximizing the value of the firm's stock for its shareholders. This is a broader objective than just profit maximization because it considers the firm's long-term performance and risk. It takes into account:

1) **Future Profits:** The value of a company's stock is based not only on current profits but also on its expected future profits.
2) **Risk:** Shareholders expect a return that is commensurate with the level of risk they are taking. A firm that manages risk well is seen as more valuable.
3) **Dividends and Stock Price:** The goal is to increase the company's stock price and provide a steady stream of dividends to its investors.

V. Other Important Objectives: Beyond the core financial goals, modern business firms also have other objectives that are crucial for long-term sustainability and success:

1) **Customer Satisfaction:** Satisfied customers are more likely to be loyal, make repeat purchases, and recommend the brand to others. This leads to increased sales and a positive brand reputation.
2) **Corporate Social Responsibility (CSR):** Many firms now aim to contribute positively to society and the environment. This can include ethical sourcing, sustainable practices, and community development. CSR can enhance a company's reputation, attract socially conscious consumers, and reduce legal or reputational risks.
3) **Employee Welfare and Satisfaction:** A motivated, skilled, and satisfied workforce is essential for productivity and innovation. Firms that invest in employee development and provide fair compensation often experience lower turnover and higher productivity.
4) **Innovation:** In a rapidly changing market, a firm's ability to innovate and adapt to new technologies and consumer preferences is critical for its survival and competitive advantage.

5.2. Benefits of ESG Consideration in Business Strategy

Integrating Environmental, Social, and Governance (ESG) factors into business strategy is no longer just a trend; it's a critical component for long-term success and sustainability. The benefits extend far beyond a company's public image, influencing its financial health, operational efficiency, and overall resilience.

1. Improved Financial Performance and Risk Mitigation: ESG considerations can directly lead to a company's improved financial performance. By focusing on environmental factors, companies can reduce costs through increased operational efficiency, such as lowering energy consumption and minimizing waste. For example, investing in renewable energy or more efficient manufacturing processes can lead to significant savings on utility bills and raw materials. Additionally, a strong ESG profile can reduce a company's risk

exposure. Firms that proactively address climate risks, labor disputes, or governance failures are less likely to face costly litigation, regulatory fines, or reputational damage. This stability makes them more attractive to investors, often resulting in a lower cost of capital and better access to financing.

2. Enhanced Reputation and Brand Value: In today's market, consumers, employees, and investors are increasingly mindful of a company's societal impact. A strong commitment to ESG principles builds trust and credibility, which can lead to enhanced brand value and a better reputation. Consumers are often more willing to support and pay a premium for products from companies they perceive as ethical and responsible. Similarly, a positive reputation for social and environmental responsibility can be a major factor in attracting and retaining top talent, especially among younger generations who seek purpose-driven work.

3. Attracting and Retaining Talent: A company's ESG performance is a powerful tool for talent management. Employees, particularly millennials and Gen Z, want to work for organizations whose values align with their own. Companies with strong social and governance practices—such as fair labor policies, diversity and inclusion initiatives, and transparent leadership—are more likely to attract and retain skilled employees. A sense of purpose and a positive work environment can boost employee morale, engagement, and productivity, while reducing turnover rates.

4. Driving Innovation and New Market Opportunities: ESG challenges can be a catalyst for innovation. By focusing on sustainability, companies are pushed to develop new, greener products and services, creating new revenue streams and market opportunities. For instance, a commitment to reducing a product's carbon footprint might lead to the creation of a more sustainable packaging material that can be sold to other businesses. These new solutions can give a company a competitive advantage and position it as a leader in its industry. For example, Tata Motors in India has been proactive in developing electric vehicles, aligning with national and global sustainability goals and positioning itself as a leader in the transition to clean energy transportation.

5. Better Access to Capital: Investors are increasingly using ESG data to evaluate a company's long-term sustainability and risk. A high ESG rating can make a firm more appealing to a growing pool of socially responsible investors and can lead to a lower cost of capital. Many investment funds and financial institutions are now screening companies based on their ESG performance, which means companies with poor ratings may be overlooked or face higher borrowing costs. Essentially, a strong ESG record signals to the market that a company is well-managed and prepared for the future.

5.3. Steps included Integrating ESG in Business Strategy

Integrating Environmental, Social, and Governance (ESG) into business strategy is a multi-step process that moves a company from a reactive, compliance-focused mindset to a proactive, value-creating one. It involves embedding environmental, social, and governance factors into the core of how a business operates.

1. Conduct a Materiality Assessment: The first and most critical step is to identify which ESG issues is **most material** to your business. This isn't a "one-size-fits-all" approach; a technology company key ESG concerns, will differ from a manufacturing company. This is "double materiality" assessment ensures you focus on issues that are both financially relevant and important to your stakeholders. Engage with key groups like investors, customers, employees, and suppliers to get their perspective.

2. Set Clear and Measurable Goals: Once you've identified your key ESG issues, you must set specific, measurable, achievable, relevant, and time-bound (SMART) goals. These goals should directly address the material issues identified in the previous step.

1) **Environmental:** A company might set a goal to reduce its greenhouse gas emissions by 30% by 2030 or switch to 100% renewable energy by a specific date.
2) **Social:** Goals could include increasing workforce diversity by a certain percentage, improving employee retention, or establishing a supplier code of conduct to ensure fair labor practices.
3) **Governance:** Goals might involve increasing the number of independent board members or aligning executive compensation with ESG performance metrics.

3. Integrate ESG into Core Business Functions: This is the phase of action. ESG objectives must be embedded into the company's daily operations and decision-making processes, not treated as a separate, isolated initiative.

1) **Supply Chain:** Integrate ESG criteria into your procurement process, favoring suppliers with strong labor and environmental standards.
2) **Operations:** Implement energy efficiency measures, waste reduction programs, and sustainable production techniques.
3) **Product Development:** Design new products with sustainability in mind, using recycled materials or creating circular business models.
4) **Human Resources:** Weave social goals into HR policies, focusing on diversity, equity, and inclusion (DEI), employee well-being, and talent development.

4. Monitor, Measure, and Report Performance: A strategy is only as good as its execution and the ability to track progress. Establish key performance indicators (KPIs) to measure company ESG performance against company goals.

1) **Data Collection:** Centralize and manage ESG data from various departments (e.g., energy consumption from operations, employee data from HR).
2) **Reporting Frameworks:** Use recognized frameworks like the Global Reporting Initiative (GRI), Sustainability Accounting Standards Board (SASB), or the Task Force on Climate-Related Financial Disclosures (TCFD) to guide company disclosures.
3) **Transparent Communication:** Regularly publish your ESG progress in an annual sustainability report. This transparency builds trust with stakeholders and helps company identify areas for continuous improvement.

5. Foster a Culture of Accountability: For ESG integration to be successful, it must be championed from the top down.

1) **Board-level Oversight:** The board of directors and senior leadership must be actively involved in setting and overseeing the ESG strategy.
2) **Employee Engagement:** Educate and train employees on the importance of ESG and their role in achieving the company's goals. Encourage feedback and participation to build a shared sense of purpose.
3) **Incentive Alignment:** Link performance and compensation for managers and executives to the achievement of ESG targets to ensure accountability and drive behavior.

5.4. Challenges in ESG Integration

While the benefits of Environmental, Social, and Governance (ESG) integration are clear, companies often face significant challenges when trying to embed these factors into their business strategies. The challenges are as follows:

I. Data and Measurement Challenges: This is often the most significant hurdle. Unlike financial data, which has well-established accounting standards, ESG data is often qualitative, non-standardized, and difficult to measure.

1) **Lack of Standardized Metrics:** There's no single, universally accepted set of metrics or a global reporting framework for all ESG factors. This makes it difficult for companies to know what to measure, how to collect data, and how to compare their performance with competitors.

2) **Data Collection and Quality:** ESG data is often siloed across different departments (e.g., HR for social data, operations for environmental data), making it hard to collect, verify, and consolidate. Companies may also struggle with the **credibility and reliability** of data, especially from their supply chains.

3) **Defining and Quantifying Risk:** While it's easy to discuss ESG risks, it's often hard to quantify their financial impact. For example, how do company put a number on the risk of reputational damage from a social issue or the long-term financial impact of climate change on a physical asset?

II. Strategic and Cultural Barriers: Integrating ESG is not just a technical exercise; it requires a fundamental shift in a company's culture and strategy.

1) **Green washing and Lack of Authenticity:** A common challenge is treating ESG as a public relations exercise rather than a genuine business priority. This leads to **green washing**, where a company makes unsubstantiated or misleading claims about its sustainability efforts, which can severely damage its reputation when exposed.

2) **Lack of Leadership Buy-in:** Without strong commitment and oversight from the board of directors and senior management, ESG initiatives are often seen as "add-ons" rather than core to the business.

3) **Internal Resistance:** Employees may resist ESG integration if they view it as an additional burden on top of their existing responsibilities. A lack of awareness, training, and clear communication can prevent employees from understanding their role in the ESG strategy.

III. Regulatory and Market Complexity: The external environment presents its own set of challenges, from evolving regulations to a fragmented market.

1) **Evolving Regulatory Landscape:** The rules and regulations around ESG reporting

are constantly changing and differ significantly by country and region. This can be particularly challenging for multinational corporations that must comply with multiple, often conflicting, frameworks.

2) **Multiple Reporting Frameworks:** Companies are often faced with a dizzying array of ESG frameworks and standards, each with different requirements and focuses. Choosing which ones to follow and reporting against all of them can be a complex and resource-intensive task.

3) **Investor Pressure vs. Short-term Profit:** While many investors are demanding more ESG transparency, some companies still face pressure to prioritize short-term financial gains over long-term, potentially costly, ESG investments. This creates a tension between shareholder expectations and a sustainable business strategy.

5.5. Meaning, Definitions, Formulas and of Accounting Profit and Economic Profit

Accounting profit and economic profit are two different ways to measure a company's profitability, distinguished primarily by the types of costs they consider.

Accounting Profit- Meaning: Accounting profit, also known as net income or bookkeeping profit is the total revenue a company earns minus its explicit costs. Explicit costs are the direct, out-of-pocket expenses that a business incurs, which are easily quantifiable and recorded in financial statements.

Definition: It's the profit figure that a business reports on its income statement. It's calculated according to Generally Accepted Accounting Principles or other standard accounting rules.

Examples of Explicit Costs :

1) Wages and salaries
2) Rent and utilities
3) Raw materials and inventory
4) Depreciation of assets
5) Interest payments and taxes

Accounting Profit = Total Revenue - Explicit Costs

Economic Profit Meaning: Economic profit is a more comprehensive measure of profitability. It considers both the explicit costs and implicit costs, which are not recorded in financial statements. Implicit costs are the opportunity costs of using resources for a

particular purpose, representing the value of the next best alternative that was foregone.

Definition: It's the difference between total revenue and the total opportunity cost of all inputs used. This metric is used by economists to determine if a business is truly efficient and making the best use of its resources. A positive economic profit indicates that the business is earning more than it could in its next best alternative.

Examples of Implicit Costs :

1) The salary the business owner could have earned working for someone else.
2) The potential rental income from a building or land the company owns and uses for its operations.
3) The interest a company could have earned by investing its capital elsewhere instead of using it to fund the business.

Economic Profit=Total Revenue-(Explicit Costs+Implicit Costs)

Economic Profit=Accounting Profit-Implicit Costs

5.5.1. Differences between accounting profit and Economic Profit

DIFFERENCES

Feature	Accounting Profit	Economic Profit
Costs :	Only explicit costs (e.g., wages, rent, raw materials)	Both explicit and implicit costs (e.g : opportunity cost).
Purpose	To measure short-term financial performance and fulfill legal & tax reporting requirements	To assess the true profitability and efficiency of a business's resource allocation in the long run.
Value	It is almost always greater than or equal to economic profit, as it doesn't subtract implicit costs	It can be positive, zero (known as normal profit), or negative
Audience	Primarily for accountants, investors, creditors, and government agencies	Primarily for business owners and managers for making strategic decisions
Basis	Based on GAAP and financial statements	Based on economic theory

5.6. Break Even Point

The break-even point can be defined as a point where total costs (expenses) and total sales (revenue) are equal. Break-even point can be described as a point where there is no net profit or loss. The firm just "breaks even. "Any company which wants to make abnormal profit, desires to have a break-even point. Graphically, it is the point where the total cost and the total revenue curves meet.

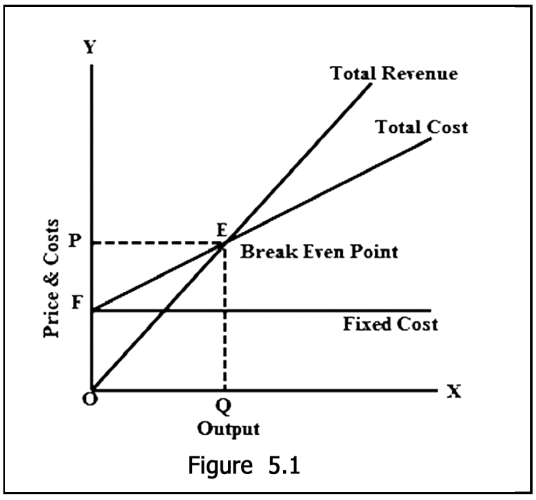

Figure 5.1

The origins of break-even point can be found in the economic concepts of "the point of indifference." The break-even analysis, in its simplest form, facilitates an insight into

the fact about revenue from a product or service incorporates the ability to cover the relevant production cost of that particular product or service or not. Moreover, the break-even point is also helpful to managers as the provided info can be used in making important decisions in business, for example preparing competitive bids, setting prices, and applying for loans. Break even shown in figure 5.1

Adding more to the point, break- even analysis is a simple tool defining the lowest quantity of sales which will include both variable and fixed costs.

Moreover, such analysis facilitates the managers with a quantity which can be used to evaluate the future demand. If, in case, the break-even point lies above the estimated demand, reflecting a loss on the product, the manager can use this info for taking various decisions. He might choose to discontinue the product, or improve the advertising strategies, or even re-price the product to increase demand.

In the figure 5.1 total revenue and total cost intersect each other at point E, by producing OQ output. The business firm produces less than OQ output; in this stage total revenue is less than total cost. The business firm incurring losses up to point E. When the firm is producing OQ of output the total cost equal to total revenue hence point is E Break even point.

5.7. Role of Artificial Intelligence in Profit Optimisation

Artificial intelligence (AI) plays a pivotal role in profit optimization by targeting both sides of the profit equation: **revenue growth** and **cost reduction**. AI's ability to analyze vast datasets, automate complex tasks, and generate actionable insights allows businesses to make smarter, more efficient decisions that directly impact their bottom line.

1. Increasing Revenue: Artificial intelligence drives revenue growth through enhanced customer understanding and smarter market strategies.

1) **Personalization and Customer Experience:** AI algorithms analyze customer data, including browsing history, purchase behavior, and demographics, to create highly personalized experiences. This includes targeted marketing campaigns, tailored product recommendations (like Netflix and Amazon's suggestion engines), and personalized customer service through AI-powered chatbots. This personalization can significantly increase customer engagement, satisfaction, and ultimately, sales.

2) **Dynamic Pricing:** AI enables dynamic pricing models that adjust product prices in real-time based on a multitude of factors, such as demand, competitor pricing, inventory levels, and even time of day. This ensures that a business is always selling at the optimal price point to maximize revenue. For example, ride-sharing services and airlines use dynamic pricing to respond to real-time supply and demand.

3) **Sales and Marketing Optimization:** AI can predict customer churn and identify high-value leads, allowing sales teams to focus their efforts on the most promising opportunities. In marketing, AI can optimize advertising spend by determining the most effective channels and content, ensuring a higher return on investment (ROI) for marketing campaigns.

2. Reducing Costs: Artificial intelligence helps reduce costs by improving operational efficiency and minimizing waste.

1) **Automation of Repetitive Tasks:** AI and robotic process automation (RPA) can automate routine, time-consuming tasks such as data entry, invoice processing, and customer service inquiries. This reduces the need for manual labor, minimizes human error, and frees up employees to focus on more strategic, high-value work.

2) **Predictive Maintenance:** In manufacturing and logistics, AI analyzes data from sensors on machinery to predict when equipment is likely to fail. This allows companies to perform maintenance proactively, preventing costly breakdowns, reducing downtime, and extending the lifespan of assets.

3) **Supply Chain and Inventory Management:** AI-powered predictive analytics can forecast demand with high accuracy. This helps businesses optimize inventory levels, reducing the costs associated with overstocking (storage, spoilage) and under stocking (lost sales, expedited shipping). It can also optimize logistics, finding the most cost-effective and efficient delivery routes.

5.8. Working of Artificial Intelligence based Pricing Models

Artificial intelligence-based pricing models, often referred to as **dynamic pricing** or **algorithmic pricing**, work by using machine learning algorithms to analyze vast amounts of data and determine the optimal price for a product or service in real time. Unlike traditional, rule-based pricing systems, AI models can learn and adapt to a wide range of factors simultaneously, enabling them to make highly accurate and autonomous pricing decisions.

I. Data Collection and Analysis: The process begins with collecting and processing a massive amount of data from various sources, both internal and external. This data is the "fuel" for the AI model.

1) **Internal Data:** This includes historical sales data, inventory levels, production costs, marketing campaign performance, and product attributes.
2) **External Data:** This is a key differentiator of AI pricing. It includes real-time competitor prices (often scraped from their websites), market demand, seasonality, local events, weather, consumer browsing behavior, and even social media sentiment.

II. Predictive Modeling and Optimization: Once the data is collected, machine learning models (such as regression, decision trees, or neural networks) are trained on it. The AI's core function is to build a mathematical model that identifies the complex relationships between all these variables and the optimal price.

1) **Forecasting Demand:** The model predicts how changes in price will affect demand. It essentially calculates the **price elasticity of demand** for each product, service, or customer segment.
2) **Determining Optimal Price:** The model's primary goal is to find the price that maximizes a specific business objective, whether it's profit, revenue, or market share. It continuously runs calculations to find the ideal price point that balances these goals in real time. For example, it might lower a price to increase sales volume and clear inventory or raise a price during a period of high demand to maximize profit.

III. Real-Time Adjustments and Feedback Loop: A key strength of AI pricing is its ability to make instant, autonomous adjustments. The system doesn't just provide a one-time recommendation; it's a continuous, self-improving process.

1) **Automated Repricing:** The model's calculated price is automatically sent to the e-commerce platform or point-of-sale system. This allows businesses to reprice products thousands of times a day, responding instantly to market shifts. For example, if a competitor's price changes, the AI can immediately adjust company price to remain competitive.
2) **Continuous Learning:** The AI model uses the results of its pricing decisions as new data, creating a feedback loop. For instance, if a price change leads to an unexpected increase in sales, the model learns from this outcome and incorporates that information into its future pricing calculations, making it smarter over time.

5.9. Types of Artificial Intelligence based Pricing Models

AI-based pricing models use machine learning to analyze vast amounts of data and adjust prices automatically to meet specific business objectives. These models move beyond simple rules-based systems to make complex, data-driven decisions in real time.

1. Dynamic Pricing: This is the most common AI pricing model. It's a strategy where prices are adjusted in **real-time** based on factors like demand, supply, competitor prices, and other market conditions. The goal is to maximize revenue or profit by ensuring the price is always optimal for the current market situation. Airlines, ride-sharing services, and e-commerce companies like Amazon are well-known users of this model. AI algorithms analyze real-time data on everything from competitor promotions to time of day and consumer behavior to predict how changes in price will impact sales. It identifies the ideal price point to balance high demand with profit margins.

2. Personalized Pricing: Also known as **price discrimination**, this model uses AI to tailor prices to **individual customers** or customer segments. The price a customer sees is based on their unique data, such as browsing history, purchase behavior, location, and even the device they are using. Machine learning models predict an individual's **willingness to pay** for a specific product or service. The price is then set to be the highest amount that customer is likely to pay without abandoning their purchase. This model is often used to offer personalized discounts or to identify customers who will accept a higher price.

3. Competitive Intelligence Pricing: This model focuses on using AI to gain a competitive advantage by constantly monitoring and reacting to **competitors' prices**. The AI scrapes data from competitors' websites to understand their pricing strategies, promotions, and positioning in the market. The AI system acts as a high-speed analyst, tracking thousands of products and their prices across competing platforms. Based on this intelligence, it can automatically adjust company prices to be more competitive—for example, by matching a lower price or by setting a slightly higher price on products where a competitor is out of stock.

4. Reinforcement Learning-based Pricing: This is a more advanced and sophisticated approach where the AI learns to set prices through **trial and error**. The AI is an "agent" that interacts with its "environment" (the market) and receives a "reward" (e.g., profit or revenue) for its actions (price changes). Instead of being given a pre-existing dataset to learn from, the model experiments with different prices and learns from the outcome of each one. For example, it might try a lower price to see if it increases sales enough to boost total profit, and if so, it will "remember" to do that in similar situations. This model is highly effective in dynamic, unpredictable markets.

5.10. Advantages and Disadvantages of AI based Pricing Models

AI-based pricing models offer significant advantages in profit optimization and competitive strategy but also present notable disadvantages related to implementation, ethics, and customer perception.

Advantages of AI-based Pricing Models: AI pricing models offer an unparalleled level of speed, accuracy, and adaptability that traditional methods can't match.

1. **Maximized Profit and Revenue:** AI models can analyze a vast number of variables in real time—such as demand, competitor prices, and inventory levels—to find the optimal price point. This allows businesses to raise prices during periods of high demand to capture more revenue and lower prices during lulls to boost sales, thereby maximizing overall profit.
2. **Real-Time Adaptability:** The market is constantly changing. AI pricing systems can react instantly to shifts, like a competitor's price change or a sudden increase in demand due to an event. This agility helps companies stay competitive and capitalize on opportunities as they arise.
3. **Enhanced Efficiency:** AI automates the complex and time-consuming process of price management. This reduces the need for manual work, minimizes human error, and frees up pricing analysts to focus on more strategic initiatives.
4. **Improved Customer Segmentation and Personalization:** AI can identify distinct customer segments and their willingness to pay. This enables companies to offer personalized pricing or discounts, which can increase conversion rates, customer satisfaction, and loyalty.

Disadvantages of AI-based Pricing Models: Despite the benefits, implementing and managing AI pricing models comes with significant challenges and risks.

1. **Data and Implementation Challenges:** The effectiveness of any AI model is dependent on the quality and quantity of its data. "Garbage in, garbage out" is a major risk. Poor or incomplete data can lead to inaccurate pricing decisions. Furthermore, the initial investment in technology, infrastructure, and skilled personnel is high, making it a significant barrier for smaller businesses.
2. **Ethical and Transparency Concerns:** AI pricing models, especially those using personalized pricing, can raise serious ethical concerns. When customers discover they've paid a different, and often higher, price for the same product as others, it can lead to feelings of unfairness and a loss of trust. This lack of transparency can result in a significant backlash and reputational damage.
3. **Risk of Price Wars:** AI models are often trained to be highly reactive to competitor pricing. If multiple companies in an industry use similar AI pricing models, it can trigger a rapid, downward spiral of price matching, leading to a "race to the bottom" that erodes profit margins for everyone.
4. **Lack of Contextual Understanding:** While AI can process data at an incredible scale, it lacks human intuition and contextual awareness. It might not understand that a competitor's price drop is a short-term promotion or that a surge in demand is due to a one-time viral video. Without human oversight, these models can make irrational pricing decisions that could harm the business.

Short Type Questions :

1. Break Even Point
2. Accounting profit
3. Economic Profit
4. Challenges in ESG integration

Essay Type Questions :

1. Explain the Objectives of Business Firm
2. Describe the Benefits of ESG consideration in Business Strategy
3. Describe the Steps included integrating ESG in Business Strategy
4. Bring out the Role of AI in Profit Optimization
5. Explain Working of AI based pricing models
6. Explain the Types of AI based pricing models

ఆహా.. అక్కెనపల్లి మీనయ్య

పోటీ పరీక్షలకు సిద్ధమవుతున్న వారికి పుస్తకాలు అందజేస్తూ..

నీలగిరి, న్యూస్‌టుడే: 'చిన్నప్పుడు ఉపాధ్యాయుడు కొట్టారని బడి మానేస్తే.. అనంతరములు అనే సారు నేను కొట్టను అని వచ్చి బడికి తీసుకెళ్లారు.. తోటి వారితో పోటీ పడినప్పుడు తెలిసింది చదువు విలువ.. ఎంత కష్టం వచ్చినా చదువు ఆపలేదు.. ఎంఏ ఎకనామిక్స్ పూర్తి చేసి ఉపాధి కోసం కండక్టర్ ఉద్యోగంలో చేరాను.. కానీ ఉపాధ్యాయుడు కావాలనే కోరికతో జూనియర్ అధ్యాపకునిగా చేరా. . ఉద్యోగంలో విశ్రాంతి పొందినా విద్యార్థులకు బోధన ఆపకూడదని ఆన్‌లైన్‌లో శిక్షణ ఇస్తున్నాను..'.. అని చెబుతున్నారు అక్కెనపల్లి మీనయ్య. ఆయన్ను ఆదర్శ అధ్యాపకుడని శిష్యులు ముద్దుగా పిలుచుకుంటారు. ఈయన వద్ద ఎకనామిక్స్‌లో మెలకువలు తెలుసుకుని దేశంలోని వివిధ విశ్వవిద్యాలయాలు, విద్యాసంస్థలలో ఎకనామిక్స్ బోధకులుగా 830 మంది ఉన్నారు. వేలాది మంది ప్రభుత్వ ఉద్యోగాల్లో స్థిరపడ్డారు.

ప్రస్థానం ఇలా ...

మీనయ్యది నార్కట్‌పల్లి మండలం గోపాలయిపల్లి గ్రామం. విద్యాభ్యాసం అంతా ప్రభుత్వ విద్యాసంస్థల్లోనే సాగింది. ఇంటర్, డిగ్రీ, ఎంఏ ఎకనామిక్స్ నల్గొండలో పూర్తి చేశారు. పేద కుటుంబం కావడంతో ఉపాధి కోసం కండక్టర్ ఉద్యోగంలో చేరారు. ఉపాధ్యాయ వృత్తిపై ఉన్న మమకారంతో 1982లో జూనియర్ లెక్చరర్‌గా బాన్సువాడలో చేరారు. నాటి నుంచి ఆయన విద్యార్థుల కోసం అనేక ప్రయోగాలు చేస్తూ ఎకనామిక్స్‌లో అనేక మెలకువలు తెలియజేస్తూ బోధించేవారు. ఆయన ఇంటర్, డిగ్రీ చదువుకున్న బాలుర జూనియర్ కళాశాలలోనే జూనియర్ అధ్యాపకునిగా, ఎన్జీ కళాశాలలో డిగ్రీ అధ్యాపకునిగా పనిచేశారు. పరీక్షల్లో విజయం సాధించేందుకు అనేక పుస్తకాలు రూపొందించారు. నేటికి మీనయ్య తయారు చేసిన సిలబస్‌ను ఇంటర్, డిగ్రీ, పీజీలో విద్యార్థులకు బోధిస్తున్నారు.

మిత్రులతో కలిసి ఫోరం ఏర్పాటు

ఎకనామిక్స్ అధ్యాపక మిత్రులతో కలిసి 2004లో ఎకనామిక్స్ ఫోరం ఏర్పాటు చేశారు. సీపీఎం నాయకుడు మల్లు వెంకటనర్సింహారెడ్డి జ్ఞాపకార్థం ఏర్పాటు చేసిన ఎంవీఎన్ ట్రస్టు ద్వారా నిరుద్యోగులకు శిక్షణ ఇచ్చారు. కరోనా తర్వాత ఆఫ్‌లైన్ క్లాస్‌లు నిర్వహించడానికి ఇబ్బందిగా మారడంతో ఆన్‌లైన్ క్లాసులు ఏర్పాటు చేశారు.

శాశ్వత కార్యక్రమంగా ఉండాలని... మీనయ్య

పేద విద్యార్థులు వృద్ధిలోకి రావాలని అనుకున్నా. ఎంవీఎన్ ట్రస్టు సహకారంతో ఎకనామిక్స్ పీజీలో సీటు కోసం ప్రత్యేక శిక్షణ ఇచ్చే వాళ్లం. వీరితో పాటు నిరుద్యోగులకు ఆన్‌లైన్‌లో ఫోరం ద్వారా శిక్షణ ఇస్తున్నాం. ఫోరంలో శాశ్వత సభ్యులను చేర్పించి ఫండ్ ఏర్పాటు చేసి నిరంతరం ఈ కార్యక్రమం కొనసాగాలని ఆలోచిస్తున్నాం. విద్యార్థులు ఎక్కడి వచ్చినా బోధిస్తాం. 2012లో ఉద్యోగ విరమణ పొందాను. అయినా పాఠాలు చెప్పడం ఆపలేదు. ఆర్థిక పరిస్థితి బాగాలేక ఉద్యోగం సాధించలేకపోయాను అనే బాధ నిరుద్యోగులకు రాకుండా చేయాలనే లక్ష్యంతో ముందుకు సాగుతున్నాం.

ఎంవీఎన్ విజ్ఞాన కేంద్రం స్టూడెంట్స్ విజయకేతనం

• 41 జూనియర్ లెక్చరర్స్ పోస్టులు కైవసం

నవతెలంగాణ -క్లాక్‌టవర్

ఈ నెల 25న ప్రకటించిన టీజీపీఎస్‌సీ ఎకనామిక్స్ జూనియర్ లెక్చరర్స్ ఫలితాల్లో నల్లగొండ జిల్లా కేంద్రంలోని ఎంవీఎన్ విజ్ఞాన కేంద్రం స్టూడెంట్స్ విజయకేతనం ఎగురవేశారు. మొత్తం 80 పోస్టులకుగాను ఎంవీఎన్ విజ్ఞాన కేంద్రం నేతృత్వంలో పనిచేస్తున్న 'ఎకనామిక్స్ ఫోరమ్' 41 పోస్టులు కైవసం చేసుకోవడం అభినందనీయమని ఫోరమ్ అధ్యక్షులు డా.అక్కెనపల్లి మీనయ్య మంగళవారం ఒక ప్రకటనలో తెలిపారు. దాదాపు 10 నెలలుపాటు రాష్ట్ర వ్యాప్తంగా ఆన్‌లైన్‌లో ప్రతిరోజూ 3 గంటలపాటు సాగిన విద్యార్థులు, ఫోరమ్ ఉపన్యాసకుల నిరంతర కృషి వల్ల ఈ అద్భుత ఫలితాలు సాధ్యమయ్యాయని పేర్కొన్నారు. క్రమబద్ధంగా క్లాసులు, వాటికి అనుగుణంగా సీబీటీ పరీక్షలు నిర్వహించడం విజయానికి దోహదం చేసిందన్నారు. గురుకుల జూనియర్ లెక్చరర్స్, డిగ్రీ ఉపన్యాసకుల ఫలితాల్లోనూ 12 మంది జూనియర్ లెక్చరర్స్, 10 మంది డిగ్రీ లెక్చరర్స్‌గా ఉద్యోగాలు పొంది మొత్తం 63 మంది నల్లగొండ ఎకనామిక్స్ ఫోరమ్ ద్వారా ఎంపికయ్యారని తెలిపారు. ఫోరమ్ విద్యార్థులు అధిక సంఖ్యలో ఎంపిక కావడం పట్ల ఫోరమ్ అసోసియేట్ అధ్యక్షులు త్రిపురం భాస్కర్ రెడ్డి, సెక్రెటరీ షేక్ సుల్తానా, మహాత్మా గాంధీ యూనివర్సిటీ అంజిరెడ్డి, ఫాకల్టీ మెంబెర్స్ కృష్ణవేణి, సరస్వతి, వెంకటేశం, ఫోరమ్ కార్యక్రమాలను ప్రోత్సహిస్తూ అండగా ఉంటున్న ప్రొఫెసర్ ఇంద్రకాంత్ హర్షం వ్యక్తం చేశారు. ఉద్యోగాలు పొందిన వారికి ఎంవీఎన్ విజ్ఞాన కేంద్రం ట్రస్టు భాధ్యులు జూలకంటి రంగారెడ్డి, నంద్యాల నర్సింహారెడ్డి, సుధాకర్‌రెడ్డి, పుచ్చకాయల నర్సిరెడ్డి అభినందనలు తెలిపారు.

Determined she moves forward

A ROLE MODEL : Shaik Sultana, who secured the first rank in the MA (Economics) common entrance examination conducted by the Osmania University, engrossed in studies in Nidmanur.
- PHOTO: SINGAM VENKATARAMANA

Secures first rank

NALGONOA: Sheik Sulthana, a native of Nidamanur, secured the first rank in the common entrance examination-2009 conducted by the Osmania University for admission to MA (Economics) course. Nalgonda Economics Forum Convenor A. Meenaiah said that Sulthana enrolled for the free coaching conducted by the forum.

- Staff Reporter

Undeterred by poverty and domestic work, Shaik Sultana, a married woman of Nidmanur, is excelling in her studies with rock solid determination.

Sultana secured first rank in the highly competitive PG common entrance examination-2009 conducted by the Osmania University for admission into MA (economics) course.

A daughter of an agriculturist and wife of a driver, Sultana surpassed all the hurdles posed by poverty with a strong will and completed her degree in first class from the Government Women's Degree College in Nalgonda.

She resumed her studies few years after her marriage and joined Intermediate. Sultana bagged the Prathibha award by securing the top marks in the Intermediate (HEC) group in the entire district.

Later, she pursued her degree after giving birth to a baby boy. She proved her calibre by securing top rank in the MA (economics) common entrance test of Osma-nia University.

"I owe a lot to the constant encouragement from my lecturers and principal", Sultana remarked and said "I credit my success in the PGCET-2009 to the free coaching given by the Economics Forum". I would like to write Group-I and other competitive examinations to become an officer of high repute, she said. I will secure admission in MA (Economics) in the Arts College in Osmania University by virtue of my first ran)?", she said.

I will take coaching for the competitive examinations during my stay in Hyderabad to realise my goal, Sultana said with confidence.

- P. SRIDHAR, Nalgonda

CPGET - 2025 ఫలితాల్లో ఫోరం విద్యార్థులు 1వ, 2వ, 3వ, 6వ, 12వ, 13వ, 14వ, 17వ మరియు 20వ ర్యాంకులు పొంది అద్భుత ఫలితాలు సాధించినారు.
